STATE LIBRARY.

No 51970

Extract from the Political Code.

SECTION 2296. Books may be taken from the Library by the MEMBERS OF THE LEGISLATURE, DURING THE SESSIONS THEREOF, and by other State officers at any time.

SEC. 2298. The Controller, if notified by the Librarian that any officer has failed to return books taken by him within the time prescribed by the Rules, and after demand made, must not draw his warrant for the salary of such officer until the return is made, or three times the value of the books, or of any injuries thereto, has been paid to the Librarian.

SEC. 2299. Every person who injures or fails to return any book taken is liable to the Librarian in three times the value thereof.

No person shall take or detain from the General Library more than two volumes at any one time, or for a longer period than two weeks. BOOKS OF REFERENCE SHALL NOT BE TAKEN FROM THE LIBRARY AT ANY TIME.—[Extract from the Rules.

☞The foregoing Regulations will be strictly enforced.☜

MINING AND SCIENTIFIC PRESS.

INV. 1898.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, JANUARY 3, 1880.

VOLUME XL Number 1.

Mining Companies Should Hold Reserves.

It is essentially necessary that mining companies should hold back a portion of their earnings, as a reserve fund upon which to draw for unlooked for but needed contingencies. Under the present arrangement which obtains as a general rule on the Pacific slope, when additional expenditures above the usual or ordinary amount are called for, an assessment is laid upon the capital stock, the holders of which must pay the amount assessed or lose their stock, which would be sold on forfeiture for non-payments. This method inflicts an injustice upon the holder of stock in the corporation. He has paid for his stock, and holds to that extent an individual interest in the property of the corporation. He is unable, perhaps, to pay the assessment, and thus in defiance of equity he is made to lose the money he paid for that interest. Without due process of law he is deprived of his property.

This system holds out the means by which dishonest or scheming directors can, by levying several assessments, and by keeping back from the stockholders the knowledge of new discoveries of value in the mines, so overload them by the amount assessed that they will be forced to sell, and they themselves become the purchasers, leaving the stockholders "out in the cold;" or, in other words, "freeze them out." It cannot keep in check extravagant expenditures by directors who hold but a very limited amount of stock, and who are reckless as to what they make others pay, so long as the small amount of stock they themselves hold entails but a small expenditure.

If the stock was made non-assessable, and a certain portion of it was set aside to be sold for a working capital, sufficient to fully develop the mine, men with means would be more willing and ready to purchase the stock, because they would know the full extent of the disbursement attending upon its purchase. If an additional sum should be required to continue the work of placing the mine in a paying condition, the owners of a majority of the shares of stock could vote as to the amount to be assessed to each share.

But when and while the mine should be in a paying condition, it would be just and right, instead of making a full division of the profits, to retain, say, ten per cent. of the net earnings, and invest it in Government or State bonds, as a contingent fund, as before stated. This would be a provident provision against unexpected calls for outlay, and might be the means of saving the property to the corporation in case of disaster or sudden emergency. Shafts may cave in; destruction by fire may occur; boilers may explode; barren portions of the vein may be encountered, and other unforeseen evils may arise, which will require additional outlay to overcome them, and which, were it not for the reserve fund on hand, would be insurmountable obstacles to the further prosecution of the work.

The adoption of this system would remove many existing evils, and it surely would not create any new ones. It would place mining operations upon a more sure foundation, and with a liberal reserve on hand the stock would certainly be enhanced in value. The more stability and certainty that can be attached to mining investments, the larger those investments will be; and the larger the investments in mining developments the more that industry will be sustained and advanced. If legislative action is to be applied to the control of mining operations, it would be a praiseworthy and judicious step in the right direction to enact the establishment of this system of raising the funds with which to prosecute the work. It would respect the rights of the stockholder, and would strengthen the position of the corporation. Such a system is certainly worthy of attentive consideration.

THE steamer *Borussia*, from Liverpool for New Orleans, was abandoned at sea December 2d, and it is thought that many of her passengers were drowned.

Woolford's Improved Wrench.

We illustrate on this page an improved ratchet wrench, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency by Joseph Woolford of Plymouth, Amador Co., Cal. The wrench is of that class used for pipes, nuts, unions and couplings of all kinds where pipe-tongs, or nut, monkey or ratchet wrenches can be used.

The handle of the wrench is provided with a corrugated or roughened beveled head or jaws, having slots formed on it. On this handle is fitted a sliding head which carries a peculiarly shaped adjustable jaw. This jaw is hooked or turned at its upper end and has its internal face roughened, the lower part being curved and the upper part being plain as shown. At the heel of this jaw is placed a spring, by which it may be operated as a ratchet. In adjusting the wrench to any desired work, the head is slid up on the handle until the lug on the latch is over the slot or notch desired and the spring will engage it with said notch. This secures the head in position and regulates the gripe of the jaws. For a greater or less gripe of the jaws, the outer end of the latch or catch is depressed by the thumb and the lug thus lifted out of the slot so the head may be slid up or down the handle to another slot, where, by releasing the catch, its spring will throw the lug on the latch into the slot.

In using the wrench as a ratchet in confined spaces, the object is griped by the jaws and the spring admits of a reciprocating motion being given to the handle without removing it from the object.

In grasping circular or similar shaped objects the pressure on the adjustable-shaped jaw will come in the curved face.

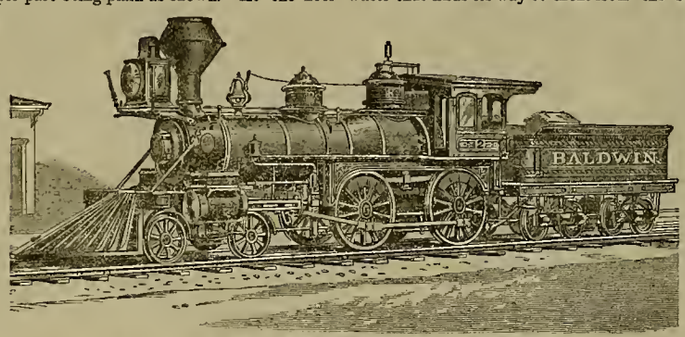
For turning square heads, bolts, etc., the upper or square portion will fit on the bolt head and the stationary jaw gripe the other side. The jaw will adjust itself to any irregularities in the object grasped.

In turning nuts, the nuts may be grasped in any position, either on the corners or the sides, and as a new hold can thus be taken on every quarter inch of surface without regard to corners, this device will work in confined spaces where no other wrench can be used.

It can be used to advantage in screwing studs into castings, as the shape allows of its use without a set-nut, thus avoiding any danger of starting the stud, when taking off the set-nut.

The ease and rapidity of adjustment to different sizes of gripe make it a very valuable bench tool, and as there are no projections on the sides, there is nothing to prevent a full turn when necessary.

The simplicity, rapidity and strength of the adjustment render the tool a very useful and practical one. There are no nuts and threads to give way under strain, and the whole is so simple that in case of breakage any blacksmith can repair it. In turning nuts it is never necessary to remove the wrench from the nut until it is tight. When the end of the stroke is reached, the handle may be slid back without removing the wrench, which on the back stroke works like a ratchet. Mr. Woolford may be communicated with at the address given above.



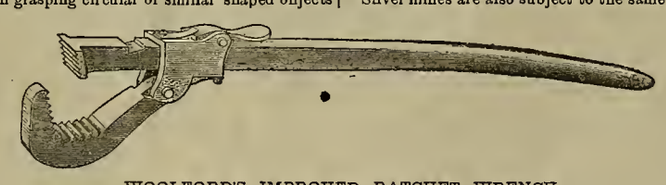
BALDWIN MANUFACTURING CO.'S LOCOMOTIVE.

Quantity of Water in Mines.

One of the most important items of expense in working many coal mines, is the enormous amount of water that has to be pumped from them. The position of the coal strata is such, that if no water rose from below them, the water that finds its way to them from the surface would still be no inconsiderable quantity. All this water has to be brought to the surface by the aid of expensive and powerful machinery, the running of which, exclusive of wear and tear, involves a heavy expense in the way of fuel and labor. In deep mines, where there is no possibility of passing the water through tunnels or drains, it entails a continuous work on the pumping engines. Some idea of the quantity to be removed may be formed from the statement of Gipsey Grove colliery in Pennsylvania, which mines about 100,000 tons of coal per annum, in which it is asserted that the water pumped out reached a million tons, or ten tons of water for every ton of coal. It is also stated that the water pumped from the Diamond colliery exceeds in tons all the coal taken from the mines in the whole Lackawanna district.

Silver mines are also subject to the same evil. When we come nearer home, we find that the Comstock mines are raising from four and a half millions to five million tons of water per year. As the depth increases, the quantity of water has also increased. This vast amount of water has hitherto been raised to, or nearly to the surface; but the recent completion of the Sutro tunnel will obviate the necessity of raising above the level of it.

From the facts given above, it will be seen that the removal of water from the mines is one of the greatest, if not the greatest item of expense. It requires the highest of engineering skill to overcome this difficulty, and were it not for the appliance of ponderous machinery, such mines as the Comstock would have to be abandoned on account of the impossibility of removing the water.



WOOLFORD'S IMPROVED RATCHET WRENCH.

BOSTON had a million-dollar fire Sunday night. The well-known publishing house of Houghton & Osgood are among the heaviest losers, their loss being about $150,000.

The Baldwin Locomotives.

The Baldwin Locomotive Works of Philadelphia are represented on this coast by Williams, Dimond & Co., No. 218 California street. The fame of the Baldwin Works is world-wide, their manufactures being largely used throughout the the United States and elsewhere. A very large order for Brazil, and another for Russia has lately been filled by these builders.

They manufacture every style of locomotive adapted for every variety of service, either narrow or broad gauge; for passenger or freight service, logging, roads, plantations, coal mines, gold mines, etc.

The following narrow-gauge roads on this coast are using Baldwin locomotives: Eureka and Palisade, Seattle Coal and Transportation Co., South Pacific Coast, Monterey and Salinas Valley, Sonoma Valley, Olympia and Tenino, etc. A specialty is made of narrow-gauge locomotives by these works.

The Baldwin steam street motor for hauling passenger cars on suburban roads, is one of the latest novelties of this manufactory. The engines are built so as to make but little noise or smoke, and are powerful enough for all purposes for which they are intended. The Geary Street, Park and Ocean R. R. Co. of this city, have recently purchased three of this style of engine; and we should advise all who find themselves in need of such power, to see the practical working of these motors before buying those of untried or unknown manufacture. This style of motor has been in use in the East for over four years past, and has given satisfaction. Williams, Dimond & Co. are prepared to furnish prices, etc., for locomotives, cars, rails, wheels and any and every description of rolling stock. The works they represent are the best outfitted in the United States for turning out the classes of work which they make a specialty. An engraving showing one of the styles of locomotives made by the Baldwin Co. appears on this page.

Mining Stocks on the Eastern Boards.

Now that the stocks of the leading mines of this coast are called at the mining boards of the Eastern cities, it is probable they will be regarded there with more consideration as to their actual merit, than to the speculative value and character which has inured to them here. The quotations here will not, after a while, materially affect their value in the Eastern markets. It may possess some slight influence, and it will undoubtedly do so, but that influence will soon pass away, and the ruling prices will fall back, there, to their intrinsic value.

Mining properties at the East are now matters for investment, with the design of making them productive. Those who put their money in them, do as they would in any other legitimate business, place it there with the intent of carrying on a paying operation. They do not invest with the view of a wild speculation out of which they will retreat as soon as they can cajole others into purchasing their stock with a wide margin of profit; they intend it as a permanent and lucrative movement on their part. The effect of this plan will be to keep such mines out of the mining boards, and leave in them only those of a purely speculative character. Those who own paying mines will prefer to have the profits go into their own pockets, instead of the coffers of outsiders.

MINING SALES.—Following sales of mines are recently reported: Eureka mine, of Como, Nev., for $50,000; Oakland, of Arizona, $15,000; Winchester, at Ten-Mile, Col., $37,000; Tip-top, Leadville, Col., $17,000; Augusta, Col., $75,000; sixth interest in Head Center, Arizona, $13,500; one-fourth of the Fairview, Leadville, Col., $17,500; one-twelfth of Miner Boy, Leadville, $50,000; half interest in Maddock, of New Mexico, $7,000; Silver King, Colorado, $3,000; Thanksgiving, Colorado, $2,000; Hecla mine, in Montana, is also reported sold for $1,000,000.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Refining Gold and Silver Amalgam.

Editors Press:—To dissipate the idea, which has arisen in the minds of several readers, that in my article, in your Christmas number, entitled "Refining of Gold and Silver Amalgam," I laid claim to hsing the inventor, or even first applier of ths chemical reaction decerihed for the purpose set forth, I would hasten to state, what, of course, every reputahle metallurgist knows, that a patent covering the chemical process for the purpose set forth was granted in 1863, and that Mr. C. A. Stetefeldt, of this city, is now about to introduce the process in perfection, as at present understood at the Ontario. What I think I did was, first, to apply it in the United States on a large scale. Eveu herein I may he mistakeu, as most wonderful things are claimed to have heen performed in Colorado; but as nothing was made puhlic to my knowledge, I will leave my claim standing to so questionable an honor. E. N. Riotte.

Refining of Gold and Silver Amalgam.

Editors Press:—From an article on the refining of gold and silver amalgam, written for the Press hy E. N. Riotte, one would suppose that Mr. Riotte was the inventor of the process described. This is not the case. The process of refining hase amalgam with chloride of copper originates with Mr. Wm. Bruckner. He firet introduced it, in the year 1862, at Morococha and Parac, Peru, South America. A patent for the United States was granted to him March 21, 1865. In the year 1867, Mr. Bruckner introduced the process iu Martini's mill, Georgetown, Colorado; also at Blackhawk, Colorado.

Before Mr. Riotte executed "his way" in Reno, he ohtained all the necessary information about this process from Mr. Reese, of Falkenau & Reese, San Francisco.

The statement "that it had been kuown for a long time"—that when quicksilver hecame "fouled" by lead or copper a slight shaking with bluestone and salt would thoroughly free it from these metals—is also without foundation.

Will Mr. Riotte bave the kindness and quote from any hook or paper, published prior to 1862, in which this method of cleaning quicksilver is mentioned?

In the fall of 1878 a series of experiments were made with this process, in the lahoratory of Falkenau & Reese, hy these gentlemen and myself, for the Ontario mill, Utah. The ohject of these experiments wae to find out if it was practicahle to regenenerate the chloride of copper from the suh-chloride by a well known reaction, namely, hy means of the oxygen of the air, sulphuric acid and salt, and to gain the surplus of copper accumulating as cement-copper. I carried out a successful experiment on a large ecale with this process at the Ontario mill in March, 1879, and the Ontario is contemplating to introduce the process. We look for Mr. Riotte's next paper on this subject with much interest.

I will finally remark that, in my opinion, Mr. Riotte overestimates the value of the process. It requires skill to execute it, and could not with safety he left in the hands of the ordinary muscular amalgamator. It is of decided advantage in such localities only where sulphuric acid can be delivered cheap, and where the hase metal in the amalgam is nearly all copper.

C. A. Stetefeldt.

Rainfall at New Almaden, California.

Editors Press:—Tbe raiu of December 19th, 4 48-100 inches, fell from 2 A. M. to 5 P. M., and was the heaviest within the memory of the oldest iuhabitant. The Alamitos creek overflowed its banke in the furnace yard, swept away heavy timhers, and threatened to destroy the bridges; but fortunately, when everything looked the worst, the waters forced tbeir way through the accumulations of furnace debris, and all danger was passed. In view of the trouhle likely to result from any addition to the unusally great quantity of furnace debris iu the creek hed, several of the furnaces were shut down in Novemher, thus decreasing the quantity of debris hy several thousand tons, otherwise the damage would have been serious.

Rainfall at the Hacienda New Almaden.

1878, total rainfall to 31st December, 1.59 inches. Observer.

The thousand paper mills of this country used in 1878 over 46,000 tons of foreign rags, valued at $2,814,515.

The Ophir.

At the recent annual meeting of the Ophir (Nevada) mining company W. H. Patton, the Superintendent of the mine, made a comprshensive report of progress during ths year. He said: "Up to Decemher 1, 1879, the Ophir mins has yielded 19,212 1400-2000 tons of ore. Of tbis ors 19,175 100-2000 tons have been milled, leaving on hand at the mill 37 1300-2000 tons, valucd hy assay at $2,916.64. This ore has all heen extracted from the so-called 'Hardy' vein above the 2100 level—1,050 tons being taken from the 1900 level, 11,847 tons from the 2000 level and 6,278 100-2000 from the 2100 level. There yet remains a large quantity of ore in place ahove the 2100 level, the amount of which cannot be accurately determined, as the formation of the vein is very irregular. The ore reduced has yielded hullion to the value of $1,283,246.07, or $66.87 per ton, the yield heing 78% of the assay valne of the ore, no allowance heing made for moisture. The value of the gold in the hullion was $564,149.57 and of the silver $719,096.50. In addition to the ore extracted there has heen raised from the mine during the past year 60,478 tons of waste rock."

On the various levels the progress is thus noted: "On the 1600 level no work has been done except to keep open the main north drift to the Mexicau line for the purposes of ventilation; and continning the drift south from our main incline to the California north line, connecting with their main lateral drift on that level. On the 1700 level we are confined to keeping the main south drift to the California north line and the drift north to the joint Mexican winze down to the 1900 level in good repair, and also jointly with the California company the east crosscut on our southern houndary, and the winze down to the 1900 level. This work was necessary to maintain our system of ventilation. On the 1900 level no work has been done except that necessary to extract the ore lying ahove that level. On the 2000 level the main north drift reached our northern boundary on December 16, 1878, at which time the work was assumed by the Mexican company and has since heen continued through the Mexican and Union Con. ground to a connection with the Union shaft. On the 2100 level the main uortheast drift from the main incline has heen exteuded to our northern boundary and counected with the joint Mexican winze sunk from the 2000 levcl. A drift was started south from the bottom of No. 1 winze in April last, and has heen run in the Hardy vein to a point 143 feet south of the winze. The ore passed through continued of good quality for a distance of 105 feet south of the winze, and from thence to the end of the drift gave low assays. Upraises have been started on tbis level witb varying success. On the 2200 level the station has been excavated and securely timhered, and ore and waste cbutes put in place. A northeast drift has heen run iu a distance of 129 fcet from the main incline and work discontinued for the present, it heing deemed advisahle to run the main north drift on the 2300 level. A drift having a southeasterly direction has been started from the station, is now in 70 feet, and will he continued in that direction to cut the Hardy vein.

"The 2300 level was reached by the maiu incline in April last. On completion of the station and ore-chutes au east drift wae run to a point 99 feet from the incline. In July last a north drift was started from the end of the east drift, and reached our northern boundary in Septemher, a distance of 370 feet. A drift was started from the end of the maiu east drift in a southeasterly direction in October last, and run a distance of 108 feet through a vein formation, hut has not reached the Hardy vein. From that point a drift has heen started in a southerly direction towards the C. and C. shaft. It is now in 148 feet. The 2400 level was reached hy the main incline in September, and on partially completing the station, a crosscut was started in a westerly direction. This crosscut is now in 267 feet, passing through a very favorahle looking vein formation having a westerly dip for a distance of 175 feet, at which point it took an easterly dip which still continues. The 2500 level was reached last month, and after cutting out a temporary station we started a north drift which will be driven with all possible speed to our northern line connecting with the winze to he sunk jointly with the Mexicau compauy at that point, and from thence it will he continued hy the Mexican and Union Con. companies to a connection with the Uniou sbaft and form the main lateral drift of this level.

"At datc of my last auuual report the main incline had attained a deptb of 30 feet helow the 2200 station. It has since heen sunk and suhstantially timhered a distance of 498 feet, on the slope (corresponding to a vertical depth of 300 feet), to a poiut 30 feet on the slope helow the 2500 station. The material passed through has heen alternate strata of vein porphyry, birdseye porphyry and quartz dipping to the west, a vein of quartz passed through near the 2300 level showing about three feet thick and giving good assays. A numher of other improvements in connection with pumping, drainage, air compression, etc., bave heen made. In addition to the extraordinary work performed and expeuses iucurred as mentioned—our main shaft has heen almost continually under repair—the ground passed throngh between the 700 and 1465 levels pressing so heavily as to require a force of at least 40 men per day to bs employed to enlarge and re-timher it and keep it in proper condition for use.

"In my last annual report I stated that tbe prohable yield of the mine during the ensuing ysar would hs more than sufficient to pay our running expanses and render assessments unnecessary. By referring to the Secrstary's statement of receipts and dishursements you will ses that notwithstanding the immense amount of work done in the mine during the year, and the extraordinary expenses incurred. my anticipations have heen more than realized. We have heen ahle to pay a dividend of one dollar per share, amounting to $100,800, and still retain a halance of $134,892.83 in the treasury.

"Our explorations in depth will be continued during the coming year with all possihle energy, and at the same time the different levels opened and the ground thoroughly prospected in all directions. The great improvement met with in the character of our ground as greater depth is attained, gives reasonahle hope for a favorahle result in that direction, while the amount of ore still in place in the Hardy vein ahove the 2100 level, and the strong probahilities of its extending some distance helow that level, give us reasonahle hopes of greater prosperity during tbe coming year."

A "Distillation Process" of Working Ores.

A gold refinery is about to go into operatiou at Buffalo for tbe treatment of refractory ores hy a comparatively new process. The old file works in that city have been secured for this purpose and are being adapted to the new business. The ores which are to he used will come from the gold and silver regions of the West, Canada and the South. Mines which, altbough very rich, have hitherto heen practically useless on account of the refractory character of their ores will now, it is promisecd, assume their real value, and he vigorously operated.

The ore is to be refined hy what is termed tbe "distillation process." The furnace is huilt like all hlast furnaces, with a pipe running nearly horizoutal to a perpendicular hrick stack. Into the pipe, near its connection with the furnace, a jet of steam is allowed to euter. The ore, after heing distilled, or, as more familiarly termed, burnt out, passes through with the steam into the hrick stack, near the intersection of which it comes in contact with a stream of cold water, which condenses the steam, and washes the metal down into a large receiving vessel filled with water. This deposit is known as per-sulphuret of gold and silver. The heat of this furnace is gained in an entirely new manner.

The ore is heated in the furnace until the slag—that is, the sediment—sbows no gold hy an assay. After the metal reaches the receiving vessel in the shape of a per-sulphuret, it is melted down with lead, and cupelled.

The cupels in which this last process is performed are made of bones, which are hurnt, then ground as fine as flour, after which they are molded into small vessels. The leaded hullion is then run into these cupels, and then set in small furnaces, known as muffed furnaces. In these the heat is hrought to ahout 4,000 degrees; the lead is oxidized, and the gold and silver are left in a pure state in the cupels.

The metal has now reached a comhination of gold and silver; and the next work is to separate these. The cupels are taken into the wet-room, where the two are disunited hy various acids—their use depending upon the nature of the compound. After tbe two are parted, they are separately put through another acid test; after which they are melted into ingots.—*American Manufacturer.*

The Spring of the Greyhound.—Readers will remember the allusious made in the Press to the discoveries concerning the action of the horse at a high rate of speed, made by Mr. Muybridge with his method of instantaneous photography. It was plainly shown that the horse assumed attitudes which no artist ever sketched and which no observer would have thought possihle. The electric camera, however, fastened the image, and there was nothing left but to accept the testimony ou the negative. According to an account in the *Call* Mr. Muybridge has applied the same agency to the motion of the dog, and with similarly astonishing results. The cramped and improbahle positions of the dog, as shown in the negatives, would scarcely he believed hy anyone who had not seen the fact recorded hy the "unerring finger of light." It is usual to delineate a greyhound extended, but these negatives, among other positions, give the animal with his limhs gathered under him, storing his strength for the spring. These pictures, which will shortly he puhlished, will he of intense interest to all dog fanciers, inasmuch as they will supply points of observation and comparison, which may lead to a hetter selection in breeding, fostering those who show the hest points, and eliminating the feebler, thus enahling scieuce to come to the aid of nature, and provide for the "survival of the fittest." The dog is got at speed hy holding him on one side, while an attendant takes a rabhit across a line drawn in front of the camera, the ground heing covered with a sheet of India-ruhher to prevent any dust or pehhles flying up to impair the clear-cut outlines of the picture; the moment the dog passes the front of the camera the fine wire is broken, the electric circuit is complete, and the trustworthy collodian has put the fleeting vision on permanent record. These dog-pictures will create eurprise in the minds of those who have only associated the ideal greyhouud with undulating and serpentine grace.

Softening Argentiferous and Auriferous Lead.

The last number of the London *Mining Journal* gives the process of desilverizing auriferous and argentiferous lead according to ths inventiou of Mr. A. Marin-y-Garcia, of Aguilas, which is conducted as usual by the introduction of metallic zinc or spelter into the fused lead after cleaning the hath from antimony, iron and other impurities, hy discharging air under pressure into the hath. The compressed air is introduced into ths lsad pan hy a metallic pipe vertically disposed in the center of the said pan at a few inches from the bottom, aud connected with a force pump which will deliver the air at a pressure of ahout 2½ atmospheres. The scums thrown up hy the action of the air are the oxides of antimony and iron mixed with lead-oxide, and may he termed oxides No. 1. The introduction of zinc or spelter into the lead produces rich scums, which are alloys of lead, zinc and silver, the proportion of zinc is one-third approximately of the scums, and nearly the whole silver of the argentiferoue lead is concentrated in them. These rich scums are subjected to the action of a hlast of air by apparatus similar to that above described, and are converted into fine oxides of lead and zinc, the silver remains unoxidized, hut intermixed in the whole mass. This oxidation must he thoroughly effected to ensure the complete snccess of the process. These scums resulting from this operation may he termed oxides No. 2. The lead which has given its silver to the rich scums or to the oxides No. 2 is contaminated with zinc, to remove which the metal is treated with a blast of air, as before described; the result will he, first, zinc scums which may he used for a new desilverizing operation; and poor oxides of lead mixed witb oxides of zinc, which may be termed oxides No. 3. The poor lead is cast into pigs, and is ready for the markct as soft lead.

The metallurgical treatment of the three kinds of oxides must next be desorihed: The oxides No. 1, finely powdered, are dissolved in concentrated vinegar (acetic acid, pyrolignous acid), the antimonial yellow oxide remaining in suspension, aud leaving the silver, if any, in the hottom of the vessel. By filtration the antimonial oxide is completely separated, and there results a eolution of acetate of lead. The oxidee No. 2, containing nearly all the silver of the lead, are treated in the same way hy a solution of concentrated vinegar, the same being actively stirred. The silver deposits on the hottom of the vessel; meanwhile the oxides of lead and zinc dissolve completely as acetates of lead and zinc in the same mauner as in the precedent case of No. 1 oxides. The silver is collected in the form of a fine metallic gray powder, washed in clean water, refiued in graphite crucihles, and molded into ingots. The douhle acetate of lead and zinc is added to the acetate of lead ohtained from oxide No. 1. With this operation the cupellation process is avoided with all its difficulties, loss of silver and lead. The oxides No. 3, poor in silver, are subjected to the same treatment, *i. e.*, dissolved in concentrated viuegar separated into two products, some silver, which deposits in the hottom of the vessel, and the douhle acetate of lead and zinc. The silver is collected with the eilver of the oxide No. 2, and the acetates are added to the other acetates.

The soft lead and the silver are, of course, the most important products, hut Mr. Marin-y-Garcia also utilizes the secondary process—that is, the autimonial oxide and the douhle acetate of lead and zinc. The antimonial oxide is a yellow pigment, a use for which will no douht he readily found. The douhle acetate of lead and zinc can receive various treatments for its further utilization. Thus hy crystallization sugar of lead can he ohtained, and the mother liquor coutaining the acetate of zinc can be treated for white zinc hy precipitating the metal with carhonate of soda, or the liquid may he treated with carbonate of soda, to ohtain white lead with some zinc white in it. The carhonates of potash and lime give the same result, hut as the acetate of soda is the matter out of which the acetic acid is generally extracted, it seems preferable to use the carhonate of soda. The result of the precipitation hy the reactive is acetate of soda, which will he crystallized; it forms a commercial salt to he sent to market.

Explosion in a Gravel Mine.—An explosion of fire-damp occurred iu the old Kansas gravel claim on Selhy flat, just ahove Chaneys, recently, hy which two men were injured, and one narrowly escaped being killed. The incline is 340 feet deep. From it extends a side tunnel 300 feet in length, which the parties engaged in reopening the property are cleaning out. They had repaired the caves and timhered it for a distance of 100 fcet from the sump, upon quitting work Monday evening. During the night a larger amount of water than usual seeped in along the old workings, and forced the foul air forward towards the incline. When two of the men went down next morning to recommence operations, one of them, Mr. Oliver, advanced along the tunnel with a lighted candle in hand. As he reached the scene of operation, the fire-damp came in contact with the flame of the candle. There was a loud explosion that hurled him to the ground violently, tearing his clothing, burning off his eyehrows and mustache, and injuring him about the face and hands. His companion, who stood at the foot of the incline, was knocked into the water in the eump, but not hadly hurt. The force of the explosion was such as to throw loose dirt up the incline and to the top of the hoisting works on the surface.

MECHANICAL PROGRESS.

Some Hints About the Treatment of Steel.

A practical worker in steel, writing to one of our exchanges, gives the following hints in reference to the treatment of tool steel. He says: "Bosses of machine and other shops, where considerable steel is used, would be astonished could they see the amount of loss to them in broken taps, dies, reamers, drills and other tools accumulated in one year. I do not mean to say that tools can be made and hardened that will not break, but I do say fully one-third, especially taps, are broken by being improperly tempered." * * * "Thousands of dollars are lost in waste of steel and loss of time by men who try to do what they never have learned.

"First of all, never heat steel in any fire, except a charcoal fire, or a lead bath, which give it a uniform heat (I mean steel tools of any kind). Rain-water is the best water for hardening, as it contains less lime than either well or river-water. Water should never be very cold for hardening tools, as the sudden contraction of the steel will cause it to crack, more especially in cutting dies, where there are sharp corners.

"To insure thorough hardness, salt should be added to the water until the same becomes quite brackish. The salt will cause the water to take hold of the steel and cool it off gradually. I find rock or fish salt to be best, though table salt will answer. The salt is also beneficial to the carbon in steel. For removing scale from steel when put into water, ivory black should be used, putting it on the steel while it is heating, and letting it remain till the steel goes into the water.

"In tempering taps, reamers, twist drills and other like tools, great care should be taken to put them in the water in a perpendicular line, and slowly, not allowing them to remain stationary in the water, as there is danger of their being a water-crack at the water-line.

"A good way to draw the temper is to heat a collar or any suitable iron with a hole in the center, and draw the tool backward and forward through it, until the right temper is obtained, which will be uniform."

A NEW PEGGING MACHINE.—A couple of young machinists of Medway, Mass., have recently completed and got into working order a pegging machine, which is destined to work a revolution in that branch of the boot and shoe industry. It is a double-row machine, so adapted that two rows of pegs can be driven at once. It carries two awls, two drivers and two strips of peg-wood. The inventors claim for their machine the following advantages: Double speed, inasmuch as it drives two pegs at once, and as the pegs are driven simultaneously in each row, the rows are sure to be perfectly parallel. The pegs of the inside row are set directly opposite the spaces between the pegs of the outside row, thus giving the boot the appearance of hand-pegging, which result cannot be attained by any other pegging machine. It can peg across the rear end of a tap-sole. The inside row can be stopped or continued at the pleasure of the operator, without stopping the machine; or, if desirable, only one row need be inserted at a time. The great fault of the old pegging machines—destruction to lasts—is obviated, and a saving of two-thirds made by this machine, as a long row for the outside and a short one for the inside can be driven at once, thus making light work for the last-puller, and avoiding all danger of breaking the shank.

STEEL-WIRE strings of pianofortes are very commonly annealed by making the wire red-hot and then plunging it into boiling water. Ordinary experience would suggest, says the *Scientific News*, that this must harden the steel in some degree, but it has been tried upon samples of steel—including mild Bessemer steel, shear steel of different qualities, and the hardest Sheffield crucible steel—and it was found that in every case, when the operation was properly performed, the steel was remarkably annealed; samples have been cut from the bar—one heated and slowly cooled by burying in ashes under a furnace grate, the other by immersion in boiling water—the result showing that, when subjected to bending tests, those which had been cooled in the boiling water would bear more severe flexure, without cracking, than the pieces which had been more slowly cooled in the ashes. They were not so soft, but were tougher and more reliable when subjected, while cold, to violent blows of the hammer.

STEEL BOILER PLATES.—Investigations have recently been made on the German railways as to the applicability of steel for boiler plates and the advantages which it possesses over iron. The conclusions drawn are not particularly favorable to the introduction of steel plates, which appear to possess certain properties giving rise to injurious tensions and cracks during the bending and riveting of the plates. The German engineers consider that, if it is possible to use good iron plates of the strength of 45,000 lbs. to 47,000 lbs. per square inch without incurring too much expense, the balance would incline to the iron plate. Of the two processes now in vogue for producing steel plates, the Bessemer process is the least suited, Siemens-Martin or crucible steel being recommended.

Corrosion of Boilers by Fatty Matters.

The Chief of the Experimental Railway Company of France, M. A. Mercier, gives, in the *Annales des Mines*, the results of some experiments upon the changes produced by fatty matters in the wrought and cast-iron parts of engines exposed to the action of steam. M. Mercier had occasion to examine in the laboratory some hard balls taken from the cylinders of steam engines, and which were generally attributed to the use of acid lubricating oil. The balls, when crushed and digested in ether, left an insoluble residue of peroxide of iron, while the soluble part was composed of oleic acid, combined with the oxide of iron mixed with a non-decomposed oil.

A series of experiments was made to determine whether the formation of this oleate of iron resulted from the use of oil more or less rancid, having an acid reaction, or whether it was the product of the decomposition of neutral fatty matter in presence of iron and of steam at a high pressure. According to these experiments, the fatty matters have no need of being acid or rancid, nor of being heated above 212° Fahr., to decompose steam in presence of iron, and thus produce oleate of iron, glycerine and hydrogen. Observations made upon steam engines which showed corrosion in those parts exposed to oil and steam, suggested the following experiment: An iron bucket containing wrought-iron chippings, thoroughly saturated with oil of colza previously neutralized, was left during eight days in a reservoir supplying steam to several steam hammers. At the expiration of this time there were taken from the bucket about 30½ cubic inches of very thick oil, which flowed with difficulty and emitted an odor similar to that produced by the action of an acid on iron; the iron was strongly corroded, and the oil—colored to a dark brown and entirely soluble in ether—contained 7% of the oxide of iron. This oleate of iron oxidized rapidly on contact with air, and, like all the minimum salts of iron, gave up some peroxide of iron; when again placed in contact with iron it attacked the iron and was thus brought back to its first state of saturation. In this manner can be explained the large proportion of non-combined peroxide of iron contained in the matter found on the valve-face of an engine at Valance, upon which an observation was made.

These facts appear to clearly explain the corrosions of certain boilers receiving fatty matters brought over from the cylinders by the exhaust steam, or used to lubricate the throttle valve of locomotives.

In locomotives the steam is generally taken from the upper part of the boiler by means of an immersed slide throttle valve; the oil used for lubricating the latter becomes saturated with iron, and being thus made heavier than water sinks to the bottom of the boiler where it attacks the iron plates, forming in them those excavations which are only found when feed-water is used of such purity as not to deposit the lime-scale that in most cases preserves the boilers.

The use of mineral oil, thickened if necessary with wax or paraffine, for the lubrication of moving parts placed in the steam, would be without doubt a good means of preventing changes in the material of such organs.

UTILIZATION OF STEEL SCRAP.—The rapid development of the use of steel for shipbuilding in Scotland, has brought out an interesting question in regard to the utilization of the large amount of steel scrap which the shipyards now find accumulating on their hands. It appears that the shipbuilders were much dissatisfied with the low rates paid them by the Steel company of Scotland, the chief producer of steel and only user of scrap who were not willing to take it back at less than scrap iron. The question is now solved, it seems. A Coathridge ironmaster found that he could work it up into rods almost as easily as scrap iron, but his experience showed him that it required a much higher heat to weld the pieces into a solid billet. In testing the rods it was found that, while the average of the bars made by the Steel company of Scotland stood a tensile strain of 28 3 tons per square inch, the rods made from the steel scrap only bore a strain of 26.6 tons per square inch, with an equal extension of 20%. The bars made from the steel scrap have not been tested for their shearing strain; but it is thought that they would stand better than the Steel company's bars. The great advantage in the scrap steel is its price, as it can be produced at about £2 per ton less than steel bars direct from the steel makers. As Lloyd's and the Board of Trade only required steel to stand a tensile strain of from 24 to 26 tons per square inch, welding up and working the scrap steel into bars will, it is thought, prove a decided success.

A NOVEL MOTOR.—A novel form of motor has been invented by Dr. Fleischer, of Kiel (Germany), and applied by him to ship propulsion. The principle of the motor is the reactive water-jet, a device not new in itself, but which, our authority asserts, this inventor has materially improved. The vessel is propelled by two water-jets, without the aid of paddle-wheels, now appears plain that to be of any value for propeller, engines or rudder. The discharge-nozzles are swiveled so that they may be directed this way or that, and so control the direction of the vessel. The motor, as applied to the *Pellworm* (a vessel 75 feet long, 12 feet beam, flat-bottomed, and drawing 3½ feet of water), propels her at the rate of six knots per hour, and develops 25 horse power, or about 40% of the power of the steam used.

SCIENTIFIC PROGRESS.

A Horological Bureau.

Arrangements are now being perfected for the establishment of a horological bureau in connection with the Sheffield Scientific School at New Haven, Conn. A suitable building will be erected, a telescope mounted, clocks placed, and every possible convenience arranged to make the bureau as perfect and complete as possible. Mr. Waldo, the gentleman who is to have charge, is already upon the ground and directing the progress of the work.

There are already one or more establishments of the kind in the country—notably the one at Cambridge, which supplies the time for the railroads converging at Boston. But the supply of approximately correct time is the only use for which this and other observatories of the kind in this country have hitherto been employed, while the chief object of this new observatory, in addition to determining time, is the rating of watches, a thing which has not yet been attempted in this country.

To rate a watch is "to determine the rate of its gain or loss in respect to true time." Swiss watches are rated in Europe, and have been greatly improved thereby. No American watches have ever yet been rated, and manufacturers in this country are placed to disadvantage in consequence. Work of this kind has always been considered government work, or the work of scientific associations. It is now, for the first time, to be inaugurated here, under the direction of a liberally endowed association. This bureau will add nothing to the educational advantages of Yale, but will be simply a scientific work.

In initiating the work, after everything is in readiness, a sidereal clock will be started, as nearly correct as possible, after which observations will be made, to get absolutely correct time. In arriving at such a result, the sun is not the central point; but some of the numerous clock's stars, as they are called, whose time is known, will be selected and observations made at night, although with the larger stars observations may also be made in the day time. The sun will be abandoned, because one observation in twenty-four hours is not enough; an observation may be made with each star every twenty-four hours. New Haven time will be taken, but New York time will be furnished also. The Waltham Company will send 100 or 200 watches for rating, as soon as everything is ready. "Rating" for private parties, we presume, is paid for, and will form, to some extent, a source of revenue to the bureau. This bureau will probably furnish standard time for the whole country, as time can be sent by telegraph and computed for any known longitude.

The Practical Use of Science.

The adulteration of various articles of food have of late become so alarming, and the various processes are so skillfully conducted that the aid of science is being called in to assist in the detection of such practices, in order that the offenders may be more readily brought to justice. The French authorities are just now wrestling vigorously with those engaged in palming off upon the public a spurious article of olive oil, the adulterations of which have become so universal that it is difficult to get a pure article anywhere in the European market. According to the *Correspondence Scientifique*, the government recently referred the matter to a special committee of the Academy of Sciences, which has recommended the use of a new instrument which is called the diagometer. This instrument, which has been devised by Prof. Luigi Palmieri, has its action based on the differences in the electric conductivity of oils. Pure olive oil has very feeble conductive properties, which (as is also the case with other oils) increase with the amount of impurities added. The only oils that are known to compare to olive oil in respect to their low conductivity are the oils of pine-seed and hazel nuts; and these, fortunately, are too expensive to be used in the adulteration of the former. The conclusions of the committee on the practical value of the diagometer have not yet been announced; it is noted, however, that its use demands considerable manipulative skill. For the correctness of this abstract we refer to the London *Chemical News*.

Butter is another article to preserve the purity of which the aid of the scientist has been invoked. In reply to such a demand Herr Fisber asserts that the examination of butter by polarized light with a magnifying power of about 200 to 300 diameters, affords a much more certain criterion of its purity than a specific gravity test. Examined in this way, fictitious butter shows not only the globular drops and salt crystals characteristic of genuine butter, but likewise other more or less developed crystals. The author also finds this method may be applied to the determination of different kinds of fats, inasmuch as each of these shows characteristic colors in polarized light. Mutton tallow, for instance, always gives a blue tone; cocoa butter gives colors passing from the brightest green to the deepest red; the fat of oxen gives green and white luminous effects; while small bright green semi-lunar and vermicular bodies appear in common light. Hog's lard shows many colors, especially red and blue—yellow, which is characteristic of cocoa butter, being absent.

The Immensity of the Stars.

Le Monde de la Science has the following interesting "Considerations on the Stars," by Prof. J. Vinot: "It is known that the stars are true suns, that some of them are larger than our own sun, and that around these enormous centers of heat and light revolve planets on which life certainly exists. Our sun is distant from us 38,000,000 leagues, but these stars are distant at least 500,000 times as far; a distance that in fact is incommensurable and unimaginable for us. Viewed with the unaided eye the stars and the planets look alike; that is, appear to have the same diameter. But, viewed through the telescope, while the planets are seen to possess clearly appreciable diameters, the stars are still mere luminous points. The most powerful of existing telescopes, that of Melbourne, which magnifies 8,000 times, gives us an image of one of our planets possessing an apparent diameter of several degrees. Jupiter, for instance, which seen with the naked eye, appears as a star of the first magnitude, with a diameter of 45° at the most, will in this telescope have its diameter multiplied 8,000 times, and will be seen as if it occupied in the heavens at an angle of 100°. Meanwhile, a star, alongside of Jupiter, and which to the eye is as bright as that planet, will still be a simple dimensionless point. Nevertheless that star is thousands of times more voluminous than the planet.

"Divide the distance between us and a planet by 8,000, and you have for a result a distance relatively very small; but divide by 8,000 the enormous number of leagues which represents the distance of a star, and there still remain a number of leagues too great to permit of the stars being seen by us in a perceptible form. In considering Jupiter, or any of the planets, we are filled with wonder at the thought that this little luminous point might hide not only all the visible stars, but a number 5,000 fold greater, for of stars visible to our eyes there are only about 5,000. All the stars of these many constellations, as the Great Bear, Cassiopeia, Orion, Andromeda, all the stars of the zodiac, even all the stars which are visible only from the earth's southern hemisphere, might be set in one plane, side by side, with no one overlapping another, even without the slightest contact between star and star, and yet they would occupy so small a space that, were it to be multiplied 5,000 fold, that space would be entirely covered by the disk of Jupiter, albeit that disk to us seems to be an inappreciable point."

PRODUCING ALCOHOL BY ELECTRICITY.—Berthelo's experimental attempts to form alcohol by electricity were conducted as follows: A battery of from six to eight Bunseu elements was arranged in connection with an oscillating commutator, so as to give alternately positive and negative currents twelve to fifteen times a second to two cylinders of spongy platinum, acting as electrodes. These platinum cylinders were immersed in acidulated water, and the contacts so arranged that neither oxygen nor hydrogen was disengaged, the water being reformed as soon as decomposed. Thus regulated, the electrodes of the apparatus were immersed in an aqueous solution of glucose. In this way alcohol was formed, although in very small quantities, but it is expected that when some improvements in the apparatus are made, the process will be much more rapid.

A NEW ANTISEPTIC.—The *Journal of Chemistry* describes a new antiseptic—a double salt of borate of potassium and sodium, which is made by dissolving in water equal portions of chloride of potassium, nitrate of sodium, and boracic acid, filtering and evaporating to dryness. It gives no bad taste to food. Butter may be kept sweet by it at ordinary temperatures for a week. Meat, game, etc., dipped in a weak solution remain pure for a long time. A piece of meat well rubbed with the salt and laid away two years ago, is now in perfectly good condition. Eggs, dipped in a solution of this antiseptic, remain good for a long time.

CARBON IN COMETS.—It is generally believed that some compound of carbon exists in comets, and it has been assumed that the bright lines in the spectra of these bodies were due to that compound being in an incandescent state. G. J. Stoney has advanced another hypothesis. He suggests that the bright lines are caused by the light of the sun falling on the compound of carbon, and rendering it visible in the same way that light renders moon, the planets and other opaque objects visible, the vapor of carbon being opaque to the particular rays which appear as bright lines in its spectrum.

RECENT experiments, it is said, seem to show that chlorine, which has hitherto been classed as one of the elements, is a compound, one of the elements of which is oxygen. It is known by chemists that ozone has a higher density than oxygen in its usual state, the explanation given being that the ozone molecule has three atoms oxygen, whereas the ordinary oxygen molecule consists of but two. On heating ozone the density is decreased, and the gas becomes plain oxygen. In this case, one of the "elements" must probably be struck from the list.

Mining Share Market.

The week is a broken one owing to the New Year's Day being a legal holiday and operators appear loth to make any decided movements at the close of 1879. There was a little spurt in the market ou Monday which gave a temporary hope of a rise to the desponding ones who are looking to 1880 as the Mecca of their anticipations of better times. Still the transactions were limited and the market was decidedly mixed. Since then there has been a lack of interest althongh prices have in the main been well sustained, which has been a surprise to those who thought prices would weaken at the last of the year. The fluctuations have been light, no real buoyancy being shown and as the sales have been moderate and in small lots, no one operator has been known to make a grand strike; in fact the loss and gain have been about equal.

The general outlook on the Comstock mines is favorable. Ore is said to have been struck in the 2760 level of the Belcher in the east crosscut; it is small stringer of rich ore, and is considered promising. Connection will be soon made between the header of the Sutro tunnel and the east crosscut of the Gould & Curry and Best & Belcher on the 1700 level. In the Sutro tunnel the headers will each make about 400 feet for December. In the Lady Bryan they are finding hnnches of good ore in the incline below the 750 level.

The extreme cold weather has caused some delay in mining hy causing the hursting of water pipes and hy the general retarding influence of low temperatnre. This has been more especially marked upon the Comstock lodc, hecause the operations are so much more extensive there than elsewhere. It has also had an influence on the shipments of hullion. With the cessation of the cold wave hetter resnlts are anticipated.

We are again this week without onr usual summary of mining news from the Comstock, owing to the fact that we go to press one day earlier than customary, in order to enjoy as a holiday, New Year's day. We have, however, printed extracts from the letters of superintendents of prominent mines.

An Arizona Gold Yarn.

The Phœnix *Herald* of recent date contains a long account of the reported discovery of placer diggings of immense richness, about 90 miles northeast of Phœuix. Tho news was brought in hy a Mexican, who says that about a month ago he started out with a companion prospecting, going np Salt river. When opposite Superstition mountain, they left the river and began prospecting. While climbing np the mountain in a little gully through black sand, and down which a large stream of water had evidently run years ago, they were astonished to find that in this sand were large quantities of fine gold. In some places the sand was only about half an inch over the granite. The gold, in pieces the size of a bean and smaller, was found in the fissures in the face of the bedrock. Very little washing was necessary, and they found a little spring of water, which furnished them what they needed. They obtained about $600 worth in half a day's work. About two o'clock in the afternoon they were surprised to see an Indian woman come to the top of a gulch abovo the spring and start to como down. Upon seeing them she ran back over the hill. In less than 10 minutes they were surrounded by 50 or 60 savages. The Indians were small, and seemed to be of a different nation than any they had seen in Arizona. The Mexicans were not armed, except with knives, and the Mexican says they were almost instantly canght with lariats. The Indians took them np the mountain and put them in a cave. They tortured and killed his companion, and his fate would have been tho same hut for his escape. He succeeded in getting away with only a few knife gashes in his face. They lost their gold with all their outfit. The Indians seemed to he cavedwellers, and were evidently excited over tho place being found hy outsiders. The Mexican, when he reached town, was a pitiful sight. His hands and feet were torn and hleeding, and his faec was gashed in a fearful manner.

Proposed One-Rail Railroad.

We referred a short time siuce to the locomotive now in process of construction at the Union Iron Works, in this city, for testing the practicability of the James one-rail railroad system, and which will he completed in a few days. The Antioch *Ledger* has the following to say concerning the project: Mr. James will come to Antioch in a few days to superintend the laying of half a milo of track to make the trial test. Rouse, Forman & Co. have agreed to furnish the lumher for laying the ties and rails, and our citizens will no douht donate the lahor necessary to make the experiment. We are also in receipt of a letter from W. H. Worswick, of Grangeville, in Tnlare county, the proposed terminus of the road, stating that a number of gentlemen from that place will come to Antioch as soon as they are informed that the engine and car are completed, to he present at the trial. This is a matter all-important to Antioch if it proves successful, and as the good people of Grangeville have advanced between $2,000 and $3,000 reqnired in building the locomotive and car, our citizens can well afford to aid in laying the half-mile track. A railroad from our water front to Grangeville, a distance of 190 miles through the west San Joaquin valley, would bring a large amount of grain and other farming products to this point for shipment, and he of incalculahle advantage to this section. Warehonses for storing grain would necessarily follow, vessels would come here to receive their cargoes for foreign markets and a foundation wonld he laid for the future growth of onr town. Should the experiment fail, which those having the matter in charge do not helieve possible, it is to he hoped the farmers of the valley will conclnde to hnild a narrow-gauge road.

THE SKAGIT MINES.—Many miners have recently arrived at La Conner, W. T., who report that some prospectors are still arriving at the diggings, but they cannot stay in the mines this winter, as there are no means of subsistence. The new gold field seems to be rich, as in every place where hedrock has been reached, on three different creeks, good pay dirt has been found, and several specimens have been taken out, weighing an ounce or more each. The country is new and unexplored, and all the old miners who have heen there pronounce it an extensive gold region. But there is no use of going there before March next, as there can he nothing done. It has been very difficnlt to get to the mines this season, as the means of traveling was in canoes up the Skagit river, as far as navigable in them, and then clamhering along the cliffs of rock the halance of the way. Many men have heen drowned this fall in trying to stem the current of the river in canoes, as it is very swift. But all of this trouhle is about to he remedied, as a pack-trail through the Hope Pass will soon he completed, and pack-trains will he put on as soon as the spring opens. The route likely to he then traveled, after leaving Seattle, will he hy steamer to Bellingham hay, a distance of eighty miles, and from thence eighty-five miles through Hope Pass to the mines. Wagons can run about fifty miles of this latter distance, and thirty miles on pack animals.

THE Supreme Court has decided that indictments found hy the last Grand Jury against Charles De Young and others are valid, and the indicted parties must stand trial.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MINING SALE.—Amador *Sentinel*, Dec. 24: Daniel Doty sold an undeveloped quartz mine near Amador recently to Morgan & Tozer, of the Butte Basin company, for $1,500.

PLYMOUTH MINES.—Correspondent of the *Sentinel*: Twenty-five mines are now being worked in this county, with prospects of many more within the next year. For example, take the Empire at Plymouth, where mining and milling only costs $3 per ton ($20 on the Comstock), with a 60-ft ledge of $17 ore, thence travel three miles south to the Gover, a mine of like character, but needing, like the Empire, improved machinery. We have only about 450 stamps crushing ore from the Cosumnes river on the north to the Mokelumne on the south, yet there is room for 5,000. Work on the Baldwin mine, near Nashville, is going ahead. On the completion of the present shaft, 300 ft of cross-cutting will be done, and if the present ore-body continues—which is 18 ft wide, with assay at $11.25 per ton—proper hoisting and reduction works will he erected from time to time as may be needed. E. J. Baldwin and party were recently here and secured interests, and five other claims near the mine are now being developed.

NORTH GOVER.—*Ledger*, Dec. 27: At the annual meeting of stockholders, 40,263 shares, out of a total of 60,000 shares, were represented. The following trustees were elected for the ensuing year: John Palmer, ft. M. Ford, A. Weil, f. N. Templeton and H. B. Templeton. The company has just let another contract to Calamori & Co., to extend the tunnel from the Gover, through which it is proposed to prospect the mine, another 100 ft. When this contract is completed, the tunnel will be 54 feet inside the North Oover ground. At present small strata of broken quartz appear in the face of the tunnel.

DOWNS.—The last clean-up just made, from a crushing of 278 tons, yielded a trifle over $25 per ton.

BUTTE BASIN.—At the Butte Basin sinking operations the pumping apparatus is again out of gear, and the water holds undisputed possession of the shaft. A larger pump has been procured, and two professional divers are here to fix it in the shaft when it arrives. The land along Mill creek, ten miles above Volcano, has been extensively located for gravel mining purposes. It is reported that the ground will pay at the rate of $4 per day per man.

CALAVERAS.

QUARTZ MINING.—*Advertiser*, Dec. 25: Quartz mining in this county is looking up, and capital is rushing in as fast as good ledges are developed. The Bonanza mine, located about four miles from Copperopolis, and owned by Andrea Fontana, changed hands on the 22d inst., for the sum of $5,000 cash, to Sidney O. Brown, of San Francisco.

ANOTHER SALE.—*Citizen*, Dec. 20: Hull & Co.'s quartz mine, in El Dorado district, was sold on the 17th inst. to George F. McPherson, of Oakland, for $3,000. This claim has been prospected sufficient to prove that it is a good mine. ft is the intention of Mr. McPherson to immediately commence work.

PRIOR CLAIM.—Charles McGuirk and several others, while prospecting in the vicinity of the County Hospital, struck "pay dirt." Tho young men were congratulating themselves on having a good thing, when other parties dropped down upon them with a prior claim, they having located the same some months ago.

THE CHAMPION.—*Chronicle*, Dec. 27: Messrs. Haskins & Hadler of the Champion mine brought down the hullion resulting from a late clean-up. It weighed 367 ounces, valued at between $6,000 and $7,000. It is but a short time since we recorded a similar "output" of "amalgam" from the Champion—a fact that we refer to simply for the purpose of showing that these $7,000 clean-ups at the Champion come so closo together as to indicate a very healthy condition of the mine.

INYO.

NEW DIGGINGS.—Inyo *Independent*, Dec. 27: N. B. Mikesell writes us from Panamint that himself and others have just made a promising discovery at a point about 20 miles north of Panamint in the same range. They have organized a district there called Breyfogle. It is well supplied with wood, water and grass. From one large lode called hy the same name as the district, a number of assays were made by Smith at Panamint. The "buttons" from three of these assays are now in our possession, and finer or larger ones are rarely seen. These assays foot up respectively $3,879.48, $556.69, and $536.66. We think there is something in this new discovery, and shall be pleased to have fuller reports concerning it.

MARIPOSA.

REB BANKS.—*Gazette*, Dec. 27: This placer claim, on Merced river, has been known and indifferently worked ever since 1849, and, notwithstanding the inefficiency of means and facilities to work the same, it has produced thousands of dollars and is yet barely prospected. Col. Swadley is now actively engaged in improvements with a view to extensive mining there. He has a body of men digging a tail-race about 150 ft long from the river up to the claim, and another force employed repairing the old ditch leading from Scott's gulch about two and a half miles long, which will soon he completed. A full set of hydraulic apparatus, blacksmith and carpenter tools, etc., have been ordered. It is also contemplated taking water from the Benton Dam, about one mile above, and conveying the same by ditch and flume to the claim.

MONO.

PLACER MINES.—Bodie *News*, Dec. 23: The placer mines recently struck near the Dudley receive their supply of water from the Goodshaw, who are constantly raising with pumps from seven to ten inches, miners' measure, of water. This affords a limited supply to work the placers. When the Jupiter pumps get in operation a still further supply will he furnished. It is only a question of time about having plenty of water from the South Noonday, the Red Cloud, Stanford and Defiance to amply supply all demands, when the yield from the placer mines east of the hill will assume large proportions and hundreds of men will have profitable employment in our placer mines.

THE NEW NOONDAY MILL.—Bodie *Free Press*, Dec. 26: The day of starting the mill was reserved for Christmas. Mrs. John Parkham, wife of Superintendent Parkham, blew the steam whistle at 3 P. M. and started the monster engine in the presence of a large number of people. This mill is one of the best appointed on the coast. It has 30 stamps, 24 pans and 12 settlers. ft is run by a Harris Corliss engine of 220-horse power—the same make of engine as was used to run the machinery at the Centennial exposition at Philadelphia in 1876. Mr. J. H. Tosney, an experienced engineer, came out from the East to put up the engine, and is retained as chief engineer. The crushing capacity of the mill is 100 tons per day, and the management apprehend no difficulty in supplying it with that amount. The contractors, Messrs. G. H. Malter and Jas. Mee, commenced grading July 24th. The cost of the work is said to have been about $120,000. Mr. Jas. Mee will remain as Superintendent of the mill.

SPAULDING MILL.—Bodie *News*, Dec. 27: This mill will be finished and crushing rock by Feh. 1st. The mill building is completed and the engine set in place. Six pans are in position and three settlers. The rest of the pans and settlers are on the road.

NOONDAY.—The mine is looking as well as ever and turning out a good quality of ore for the new mill, which started up at 3 o'clock on Christmas afternoon. Everything about the mill is working smoothly.

TIOGA.—Shaft down 721 ft, having heen sunk and timhered 10 ft during the week. The bottom is still in the vein, which is about 12 ft in width, the walls being very regular and hard. The Syudicate drift is in 637 ft—an advance of 14 ft this week. The east crosscut from the Ralston winze has been advanced 12 ft this week, with several small streaks of rich ore in face of the crosscut.

SOUTH NOONDAY.—The ledge passed through at a depth of 70 ft has straightened and is now standing almost vertical, being on the east side of the shaft.

MONO.—Work at this mine is still confined to sinking. The shaft is down 515 ft. The pumps and everything about the mine are working satisfactorily.

SOUTH BELWER.—The new pumping machinery is all on the ground, and will be put in position immediately, so that sinking may be resumed on the 1st of Jan. The sinking of winze No. 1, on 350 level, is progressing favorably, and is down 174 ft. This winze has been carried down on the ledge, which is now four ft wide of good ore. This winze is being sunk for the purpose of connecting with the 550 level, so as to expedite the opening up of the mine and ventilating the lower levels.

BOSTON CON.—The shaft is down 195 ft, and the contractors will finish it to the 200 level early next week, when crosscutting and exploring both veins will be carried forward as speedily as possible.

CON. PACIFIC.—Work in this mine has gone on uninterruptedly the past week. The shaft is down 60 ft below the 400 level, carrying quartz on the east side, the vein going down nearly vertical. The assays from this increases as depth is attained, and without donbt it will add greatly to the value of this property.

RIQUERA.—Crosscutting to the ledge from the 100 level has been commenced, and now in 14 ft from the shaft, with good prospects for cutting the ledge soon.

QUEEN BEE.—East crosscut on 400 level has advanced 14 ft this week, making a total of 70 ft from the shaft. The ground passed through is looking very well, and several strata of quartz have been cut, and appearances indicate that a ledge may be struck within a week or so. Everything about the mine is in good order.

BLACKHAWK.—The shaft is down 540 ft. No change in the rock. Since last report have made 2 ft. East crosscut, bottom of winze, is in 68 ft. There has been some change in the ground, passing through quartz and clay. Everything about the mine is working well.

NEVADA.

MINING BY ELECTRIC LIGHT.—Nevada City *Herald*, Dec. 23: The mine at Mooney flat, formerly owned by the Deer Creek company, is being worked extensively hy its present owners, the Excelsior Con. company. Work is carried on in three sets of claims, operated in rotation, with two large monitors located in each set. While the water is playing in one of the claims, the miners work at drilling, blasting and breaking pipe clay in another. The dirt is very rich, so that gold can he seen plainly in most places in the blue gravel. The outlet is through a bedrock tunnel which dumps into Deer creek. The dump is excellent and will admit of working the entire claim, with no danger from blockade, as each rise of water in Deer creek carries the tailings completely away. At present 45 men are employed, hut the water is made to do most of the work. Operations are carried on both day and night, and the company has lately procured a powerful electric machine at a cost of $1,500, so that the mine is lighted with electric light. The electricity is generated hy friction and the motive power is produced by about 30 inches of water, which is taken from the main water pipe, and after being utilized is returned, so that no waste or loss occurs. The electric current is carried to the point where the light is desired by large-sized copper wires suspended similar to telegraph wires. The current is made to leap a short space from one electric candle to another to complete the circuit; it is this continuous leaping which gives ont the bright light which illuminates the mine, almost equal to sunlight. Other companies intend to introduce this innovation.

COPPER.—At the copper mine, near Spenceville, a new roasting shed 600 ft long has been erected on the hill above the shaft, and another new one is to be built, which will be 300 ft in length. The old shed in the canyon is to be torn down, as from it comes most of the offensive sulphur smoke which settles in the village. The ore at present being taken out is richer in copper than any heretofore extracted.

WASHINGTON MINE.—At the late annual meeting of this mining company, the old Board of Trustees was re-elected. The report of the Secretary shows that the company have accomplished a great deal with the means at their command, the sinking of the shaft being one of the cheapest pieces of work ever performed in the district.

THE YUBA.—*Foothill Tidings*, Dec. 27: Good reports come from the Yuha gold mine, near Washington, the controlling interest in which was recently purchased hy Col. W. K. Rodgers, of Sonoma. The main drift has developed a four-ft vein of good paying quartz, and the progress already made encourages the helief that this chute will prove a continuous and permanent one and of great value.

HYDRAULICS SHUT DOWN.—Nevada City *Transcript*, Dec 27: The recent cold weather has caused the suspension of washing in all the principal hydraulic mines of the county, including the Blue Tent, Sailor Flat, North Bloomfield, Milton, etc. Water was turned out from most of the ditches as soon as the mercury commenced to go down, but where permitted to remain in, an occasional one froze to a solid mass. Even the large Smartsville ditch, which a gentleman, who worked along it for 12 years, says was never before affected in a similar manner, is only open for a few inches along the center, and the water that rushes down is thick with broken ice and snow. It will take a couple of days of warm weather to start the mines again.

NEVADA.

WASHOE DISTRICT.

Reports condensed from official letters from the mines, dated Dec. 27th:

JULIA.—Repairs on 2000 level, south drift, are progressing favorably, and unless some unforseen accident occurs, the face of the south-west crosscut will be reached by the end of the coming week, and prospecting at once commenced. Ventilation throughout the mine has greatly improved within the last week.

WARD.—Shaft has been sunk 19 ft during the past week; total depth, 1,897 ft. Flow of water continues strong, about 135,000 gallons per 24 hours, and a very prominent change has taken place in the general formation, presenting vein material of a promising character.

CHOLLAR.—The Chollar drift west on 2400 level has been run 60 ft during the past week, making total distance from face to shaft 262 ft. The ground has been very hard, and worked badly. It has now become softer and blasts out well; material has been vein porphyry.

SILVER HILL.—During the past week the east crosscut, 1300 level, has been extended and timbered 30 ft. We also started a drift south and timbered it 10 ft, which will be used to switch off the drilling machines. Material passed through is about the same as last week, bird's-eye porphyry; a little increase of water has been encountered in the mine.

OPHIR.—Work was commenced on the west end excavation for pump tank below the 2500 station of the main incline on Thursday last. This work will interfere to some extent with sinking the incline, but will be completed as soon as possible, and the main line of pumps carried down to that point. On the 2500 level the main north drift has been advanced 24 ft, making a total length of 54 ft from the main incline, passing through a heavy vein formation which requires careful timbering, carrying some low-grade ore. On the 2400 level the west crosscut continues in vein formation. On the 2200 level the south drift has been extended 24 ft; total length, 121 ft, and is passing into a vein formation showing some quartz. On the 2100 level the north drift has been advanced 13 ft through milling ore, and is now in 230 ft from crosscut No. 1. The ore stopes continue to yield the usual quantity of good milling ore. The extreme cold weather experienced during the week has interfered somewhat with the work hy freezing up and hursting the water and air pipes, and the formation of ice in the vertical shaft, which interfered with the running of cages.

UNION CON.—On the 2000 level the joint Mexican west crosscut on the southern boundary has been extended 21 ft, and is now in 428 ft from the main north drift, passing out of the hard vein of porphyry into a softer and more kindly formation. The joint Mexican winze has been sunk and timbered 13 ft through a bird's-eye porphyry, carrying some water, and has attained a depth of 258 ft. On the 2300 level the main south drift has been advanced 22 ft, and leaving 154 ft to be run before connecting with the joint Mexican winze level. The material passed through is a bird's-eye porphyry. The drift north from the main shaft reached the Sierra Nevada ore stopes on Thursday last. This connection will enable them to commence the extraction of ore from this level as soon as the Union shaft can handle the material. On the 2400 level they are still extending the sill flour to the south and east. The drift started on a northwest course from the ore stopes has been connected with the west drift run on the north side of the Sierra Nevada incline, passing through and over the fold of porphyry which was supposed to be the west wall of the ore body, and showing high-grade ore on the other side of it, extending to and beyond the northern boundary. They have, during the week, extracted 1,110 tons of ore, of which 712 tons have been shipped to the mill, leaving 664 tons in the ore house. The third shipment of bullion, amounting to $28,173.33, will be made soon. The extreme cold weather has interfered somewhat with milling operations, and made the weekly shipment small.

BRISTOL DISTRICT.

ITEMS.—Pioche *Record*, Dec. 27: The Hillside furnace, which has been newly relined and machinery put in perfect order, will start up Monday, with a large amount of ore on dump. Work on the empel furnace is about completed, and it is expected that the refining of Hillside bullion will commence Jan. 1st. Owing to the bad condition of the quartz road from the Hillside mine to Bristol, only about 35 tons of ore is being shipped daily to the furnace.

COMO DISTRICT.

MINES ABOUT COMO.—Reno *Gazette*, Dec. 20: The Empire looks better than ever. There is no water in the mine. The mine is regarded as sold to San Francisco parties, although there has been no money paid and no transfers made. They have until Jan. 1st to decide. J. B. Shaw has been appointed manager. The North Rapidan is regarded as the second mine in the camp. It is the property of G. W. Keith, Recorder Crowningshield and C. Hobbs, who have leased it, until May 1st, to Schaffer, Lemon and Hamilton. The ledge on which they are at work is very wide. They are already in 35 ft and have not found the footwall. The rock the whole width averages $15 a ton, and is improving rapidly. The Star of the West has been leased for a year to Patridge, who built the tailings mill near Washoe two years ago. The Chieftain is opened 200 ft deep. A drift east is 15 ft of ore worth over $30. The Great Republic has a tunnel 80 ft long, which is crosscutting strings of rich ore. These are the only mines being worked. The South Buckeye folks are ready for business, but are waiting for lumber.

A RESURRECTED CLOCK.—In a deserted drift of the Star of the West mine, at Como, a clock was recently found in a pile of dumpage which had been there since 1864. Being wound up it started running and has run ever since.

GILLIS MOUNTAIN DISTRICT.

MINING NOTES.—Cor. Esmeralda *Herald*, Dec. 27: The Gillis Mountain district is situated about 30 miles north of Belleville. The formation is granite, resembling Austin mines. There are 72 claims recorded; many of which are rich on the surface. It is no uncommon thing to get assays ranging from $1,500 to $2,000 per ton. Sixteen tons worked at the Northern Belle mine, last month, yielded $500 per ton. Mines seem rich, but prospectors are poor and need a custom mill in the district, as ore is now sacked and shipped away. ft does not pay to ship anything less than $200-ore. There is an abundance of wood and water within two and one-half miles of the mines.

PYRAMID DISTRICT.

TO BE WORKED.—Reno *Gazette*, Dec. 20: The Pyramid mining company, organized in San Francisco last fall, with a capital of $50,000,000 in 300,000 shares, have been negotiating for some months with several mine owners at Pyramid, the result of which is that the Buckeye, with 1,500 ft; the Tiger, with 1,500 ft; the South Blaisdell, with 562 ft, and the Clyde, with 188 ft, have been turned over to the new company, who will pay all their debts, and give the owners 60 of the Pyramid company's shares per foot for their ground. The Pyramid company is bound to put up pumps, hoisting works, mills, etc., within a year, or return the ground to its original owners. It is proposed to begin operations at once, and to work the whole ground through the Buckeye shaft, which is down 135 ft.

SILVER STATE DISTRICT.

ORE.—*Silver State*, Dec. 27: James Doolin's 12-mule team left Winnemucca yesterday for Silver State district, loaded with lumber and mining supplies. Mr. Doolin goes to prospect the Florence claim, owned by him and Tom Cain. They intend to bring in a carload of ore for shipment when the team returns. The Florence is located six or eight miles north of Silver Hill, where the Silver Bill and other claims of more or less prominence are situated.

SILVER REEF.—Pioche *Record*, Dec 27: We learn by letter from Silver Reef that Col. Wall has purchased the hoisting works of No. 9—old Pioche mine—for the purpose of placing them on the Kenner mine at the Reef. Barbee & Van Hagen have started to build a new mill, having ordered the machinery from Chicago, which is now on the way there.

ARIZONA.

SPEAKS FOR ITSELF.—*Arizona Sentinel*, Dec. 27: The daily arrival of mill and mining machinery for new plants, and tools, supplies, etc., for those already established is a diurnal attestation to the rapid developments making in Arizona, and they speak louder than the most flattering reports our mining experts and other visitors could make in praise of the Territory as a place for investment.

SILVER KING MINE.—There are facts connected with the management of this property which invite attention, viz.: The mine purchased itself; it has paid in a certain amount of dividends; paid for a thorough systematic opening—not inexpensive either; has given steady and remunerative occupation to a goodly number of miners, mechanics and teamsters; created a thriving village, and established a nucleus for an expansive prosperity, second to none in the Territory; has been a steady and increasing factor to railroad progress since the day that the track reached to within twelve miles of the Colorado; never has asked for an assessment; never bursted a community with its stock; never has been blown over its merit, and stands to-day as a practical result of what can he done by keeping your mouth shut and attending to your own business.

HUACHUCA DISTRICT.—*Arizona Star*, Dec. 25: W. B. Scott has bonded a property in Mormon canyon for $30,000 for four months. A shaft six ft across has been sunk, which is all in ore. The bonding parties are now running a tunnel, and will tap the vein at the depth of 150 ft from the surface.

ABOUT TUCSON.—The Black Metal mine, ten miles west of Tucson, is rapidly developing. At the depth of 22 ft the metal has widened to 18 inches, while at the surface it was two inches. The assay from the top was $812; at the bottom of the shaft it assays $400 in silver, and 40% in copper. The mine is in a porphyry formation, with excellent walls. Mr. Blade, one of the owners, brought in two pieces of ore from the Linda mine on the same ledge. One assayed over $800 and the other nearly $800.

GLOBE DISTRICT.—*Silver Belt*, Dec. 27: The Irene mine has its tunnel in over 100 ft, and is promising well. The mouth of the shaft is situated 250 ft above on the mountain, and the shaft is sunk over 70 ft. It is impossible to approximate the width of the ore vein, but from indications it is safe to say that at the present depth it will reach a width of 25 to 30 ft. We are confirmed in this opinion by Mr. Mark L. McDonald and Hon. J. K. Luttrell, who visited the mine subsequently to our visit.

NEW DISTRICT.—Cor. *Herald*, Dec. 20: There have been some new discoveries made at Pro Heney's camp, better

CONTINUED ON PAGE 12.

A Profitable Gold Mine.

The Idaho Mine, Nevada County.

The Idaho mine of Grass Valley may be taken as a representative quartz mine of California. It has been worked for many years as a legitimate mining operation without any stock-dealing manipulations. The Grass Valley *Union* publishes the report of the officers of the company for the fiscal year, which will show the operations of the mine in detail. The following is the

Superintendent's Report:

To the Stockholders of the Idaho Mining Co.—GENTLEMEN: In accordauce with the by-laws of your company, I herewith submit for your consideration my annual report for the year ending December 1, 1879.

In the year now past but little has occurred to call for special notice. The air shaft from the 400 level was completed early in the summer, and during the hot weather we derived much benefit from this expenditure; but in making this opening from the surface we struck quite a stream of water—eo much that in order to get the shaft through it was necessary to put up a small engine to pump the water. This engine was worked with compressed air from our main compressor. In order to handle this water we have secured a water wheel, which will be driven by our battery water, and it is intended to have it running before the winter rains increase the water in the ground. Also as our workings increase in depth, it was found our boiler capacity for the pumping engine was insufficient, and as we could spare one boiler from the hoisting works, it was decided to remove this boiler to the pumping works. It is now in place, and a new boiler house is erected, with iron roof and sides, for safety against fire. In view of the large amount of machine work required about the works, it was deemed economical to have it done by our own workmen; accordingly a planer and lathe were purchased, and we find many advantages in having the means of doing this work under our own supervision. In order to facilitate the work in the incline and 1100 drift, it was thought advisable to put in an exhaust fan, to draw the powder emoke and bad air from this part of the works. The engine was worked with compressed air, hut as we now have a raise through from the 1000 level, the fan is no longer needed at this point, and it is now used to force air into the 1000-foot drift. During the summer we have added two iron bobs to our pumping works underground—one for a balance at the 700 level, old shaft, and one angle boh at the bottom of the main shaft. From the hottom of the main shaft we are now driving a prospect crosscut in the foot-wall to strike a stringer which went off from the ledge in the 1,000 level, about 350 feet from the ehaft.

During the year the incline from the 1000 level has been continued down 175 feet. At this distance the 1100 level is run off and is now in 188 feet from the incline. The quartz, *as was anticipated*, has beeu of a low grade, until the last 30 feet, since which it has been of fair quality; aud as we had very good quartz in the 1000 level we may expect a further improvement in this drift and the stopes connected therewith. The incline below the 1100 level is again heing sunk and is down 32 feet; hut as we are sinking in the foot-wall and have not yet hroken into the ledge, it is impossible to speak of its size or quality

We are still taking out quartz from the stopes of the 700, 800, 900 and 1000 levels. The ledge in some places is quite small, but as we are uot yet through the pay chute it is hoped it will widen out again to its usual size.

During the year we have crushed 32,370 tons of quartz. Of this 1,225 tons came from the 700 level; 8,937 from the 800 level; 6,718 from the 900 level; 10,302 from the 1000 level; and 5,151 from the 1100 level.

Total yield of 27,160½ ounces of bullion, value.	$477,450.38
Sold 132¼ tons of tailings, sulphurets and slime	4,330.96
Estimated cost working same	2,640.00
Tailings worked on shares	7,747.90
Worked 25 tons buddle sulphurets	1,503.50
Sold 71 tons buddle sulphurets	4,254.81
Estimated cost working same	1,420.00
Sale of specimens	29.00
Total yield from quartz	$490,379.61

Averaging $15.42¾ per ton; average cost of mining and milling per ton, $8.96¼.

In the disposition of our sulphurets I have to report that in two cases we have been unable to collect our money. One lot of 29 tons was sold for $65 per ton uet; this would have given us $1,885, and the other lot of 10 tons, should have yielded us $1,500. Iu both these cases it would he useless for the company to press payment at present.

[The detailed statement of expenditures is summarized, hut the aggregates will he found under the head of recapitulation.]

Secretary's Report.

George W. Hill, Secretary, submits:

RECAPITULATION.

Mill and Mining	$200,090 85
Saving Sulphurets	2,542 50
Grinding Tailings	1,653 05
Moving Boiler	950 30
New Drums for Mill boiler	512 51
New Planer and lathe	559 30
Exhaust Fan	314 88
Iron Bobs	969 06
Air Shaft	5,599 00
Main Incline	7,030 75
Prospect Crosscut	303 00
General Expenses	14,228 44
Total Expenditures	$325,875 84

Respectfully submitted,
EDWARD COLEMAN, Supt.

The Thirteenth Annual Report for the fiscal year ending Dec. 1, 1879. At the commencement of the year just closed, to wit, Dec. 2, 1878, there was in the treasury the sum of $8,502.94. By reference to the books of the company, the several monthly reports of the Superintendent, sustained by proper vouchers duly examined at each stated meeting of the Board of Trustees, the total receipts for the year, from all sources, ending Dec. 1, 1879, amount to the sum of $492,535.21, to which add cash on hand Dec. 2, 1878, $8,502.94, which makes assets for the year of $501,038.15.

The expenses for the year for all purposes, including twelve dividends, amount to	$494,325 84
Assets brought forward	501,038 15
Balance in treasury Dec. 1 '79	$6,712 31

The undersigned respectfully refers the President and stockholders to the Thirteenth Annual report of the Superintendent of the mine, and the report of the Treasurer for detailed statements of the foregoing several summaries and which are made hereunto a part of this report. Before closing this branch of the subject the Secretary deems it not inappropriate to present in epitomized form, the aggregate receipts and expenditures of the company for the past eleven years, that heing the time in which the mine has paid dividends, and, before which only prospecting was done.

Receipts from all sources for the years:

1860	$ 306,038 75
1870	183,450 23
1871	407,301 16
1872	404,035 52
1873	1,010,512 20
1874	659,023 03
1875	509,430 72
1876	573,928 31
1877	525,435 18
1878	500,449 18
1879	501,038 15
Total receipts for 11 years	$5,599,742 43

There has been paid in dividends to the stockholders as follows:

	Div.	Per cent.	Amt.
1869	11	55	$170,500
1870	7	12	31,200
1871	12	75	232,500
1872	11	52½	162,750
1873	12	220	682,000
1874	12	102½	317,750
1875	11	55½	172,050
1876	12	82½	255,750
1877	12	77½	240,250
1878	12	85	263,500
1879	12	54½	168,950

Being for 11 years 124 dividends, aggregating 872½ on the capital stock, and amounting to $2,703,200.

Treaeurer's Report.

John C. Coleman, Treasurer, presents his annual report as Treasurer of the Idaho Quartz mining company for the year ending December 1, 1879:

RECEIPTS.

By cash on hand December 2, 1878	$ 8,502 94
From 27,160½ ounces of bullion	477,450 38
Percentage from tailings and slime	5,356 65
Pan reut	1,653 05
Sulphurets	3,878 31
Sale of specimens	29 00
Sundry receipts	4,157 22
Total receipts	$501,038 15

DISBURSEMENTS.

Paid Superintendent's checks	$325,375 84
Paid 12 Dividends	168,950 00
Total Disbursements	$494,325 84
Balance cash on hand	6,712 31

A NEW ARRANGEMENT.—The Savage mining compauy are arranging to attack their mine from the front. They consider that the time has now come to utilize tbe Combination shaft. in which they have a joint iuterest with the Hale & Norcross and Chollar and Potosi folks. As soon as the west drift now heing run from said shaft on 2400 level shall have reached the proper point the Savage folks will start from it a branch drift, which they will drive to the place where their incline will come down when extended from its present terminus at the 2400 level. It will take three or four months to run the proposed drift, meanwhile the pumps will he taken out of the 2200 level, and the water allowed to have its own way. This will be bad for the Hale & Norcross folks, who have no water to interfere with their operations on their 2200 level, as they cannot handle the water unaided, and do any work. The Hale & Norcross folks will he obliged to adopt the same plan of working as the Savage company, if the latter company carry out their present programme. The plan will certainly effect a great saving to the Savage company, as when the proposed connection is made the water will flow out to the Combination shaft without trouble or expense. The change will throw ahout 90 men out of work in the Savage. The west drift from the 2400 station of the Combination shaft is now out 86 feet, and will soon reach the point from which it is proposed to run hranch drifts to the eeveral miuee, therefore it would probably be a good plan for all to start in on that level, and at once advance explorations in the virgin ground lying at that depth, leaving the ground above to be prospected after it has drained out.—*Virginia Enterprise.*

HENRY BESSEMER, the English inventor, has taken out 160 patents, almost as many as Edison, and one of them, his process of making steel, ranks as one of the most brilliant inventions of the century. It converts pig iron into steel in a few minutes, and has reduoed the price of steel rails per ton from $200 to $30. Ten times as much steel is used in the world now as was nsed prior to 1856.

The Gold Section of Montana.

The Silver Creek Country.

From the letter of a spccial correspondent of the Helena *Independent*, we make the following abstract describing the changes and progress of the Silver Creek country, in Montana: Two short years ago the writer passed up Silver creek and over the divide of the Rocky mountain range to the other side. A little trail, resembling a brown thread laid upon green velvet, wound among the lofty pines and aromatic firs. Here aud there a small, low, log cabin could be seen, the abode of some hardy placer miner or adventurous prospector, who, immured within this mountain fastness, was unconsciously but the advance guard of a teemiug population. The beautiful parks, which occasionally opened out to view, and sloning mountain sides presented to the eye a smooth, unbroken surface yielding no evidence of the presence of man. Neither pick nor shovel in the hands of excited searchers for gold had disturbed the virgin soil. It was as the Creator had left it when He prouounced His work good. But a marvelous change has come over the face of this auriferous section within the last 20 months. The rough trail has become a well-beaten thoroughfare. The rude cabins have in a measure given place to more pretentious dwellings. The once pleasing parks and smooth mountain sides are corrugated with deep cuts and long tunnels, and pierced with shafts and inclines, till they resemble the abandoned encampment of a once besieged army.

The Mines.

The rich, paying lodes in this favored locality are by no means yet numbered. It is a land of bonanzas, and it is safe to say tbat there are a dozen unearthed where one has been found. With one or two exceptions, the lodes discovered are what is generally known as "blind lodes," or, in other words, they show no surface croppings to indicate their presence. The trend or direction of the lodes is, in most instances, southwesterly and northeasterly, with a slight dip or inclination northerly of about 70°. The vein matter varies from 3 to 59 feet in width, the average being not far from 6 feet, inclosed between well-defined, smooth walls of granite. The names of the lodes which have been developed by a ehaft or tunnel at least 50 feet or more in extent, and are known to be mines of a certain market value, are contained in the following list, to wit: Penobscot, Belmont, Whippoorwill, Bluebird, Gloster, Hickey, Mt. Pleasant, Bald Butte, Drum Lumen, Peigan, Green, Peigan No. 2, Boumahon, T. F. Meagher, Mayflower, Black Hawk and Humbug. There are many more well-defined lodes which are staked, recorded and properly represented, but their development is neccssarily slow as they are owned by men who have not the means to work tbem continuously.

The Mille,

Which are solid and well built, and are provided with all the latest improvements, will not begin to meet the demand which will be made upon them in the near future. The following list comprises the names of all that are now huilt, to wit:

Name of Mill.	Stamps.
Penobscot	40
Belmont	20
Cotter & Hickey	10
Whippoorwill	10
Gloster	5
Magyar	5
Total	90

The Gloster has power and evcrytbing in place for a 10-stamp mill. It may be so counted. The gold which is now turned out of these mills amounts to no insignificant sum. When mills are erected of sufficient capacity to handle and work all the ore wbich it is reasonable to suppose may he annually brought to the surface in this splendid quartz eection, their produce will he felt in the money markets of the world. Prominent among the many mines in this Territory to which public attention has been attracted stands

The Penobscot.

This mine is developed by a shaft 250 feet in depth and 2,291 feet of levels. All the levels in the lead are connected each with the other hy winzes, throngh which a constant supply of fresh air is obtained. Firm bodies of ore are seen throughout the mine. Captain Ryan informed me that without running another foot of levels he could stope out ore enough to run the 40-stamp mill for two years. The bottom of the shaft showe a vein of clear, solid quartz, 15 feet in width, between walls as smooth as the cheeks of a maiden.

The output of ore is about 40 tons per day, jnst enough to keep the mill employed. Seventy-five men are worked under ground and 30 men in the mill and on the outside. Everything in and ahout the mill and mine goes on with the regularity of clock-work. The resident officers of the company are as follows: Capt. W. Ryan, general superintendent; Gus. Oberg, mill superintendent; P. McLaughlin, machinist; P. W. Duffield, assayer and civil engineer; J. W. Young, clerk; Jas. Dower and F. Mahoney, foremen of mine.

The Town of Vestel.

This lively little hnrg, within gunehot of the Penobscot ehaft and built upon faith in the mine, consists of two stores, four boarding-houses besides the company's house, five saloons, one shoemaker shop and quite a large number of private residences. One mile and a half below Vestel, on the road to Helena, is the town of Mt. Pleasant. The Cotter & Hickey mill is located at this place. At present it is undergoing repairs and improvements, which change it from a five to a ten-stamp mill. It will start up this week for its winter service. The town consists of one store, one saloon, two boarding-houses, a shoemaker shop, a postoffice and several private residences. A mile aud a balf below is the rustling little town of Belmont. This place consists of two stores and another in course of completion, three boarding-houses, four saloons, three billiard halls, one blacksmith shop, one butcher shop and a score or so of private residences. This place, like Vestel, is the outgrowth of faith—faith in the richness and stability of the many lodes in its immediate vicinity.

The Belmont Mine,

Which is located a short distance above the town, is probably one of the easiest, if not the very easiest, mine to work in the Territory. The trend of the lode is up the steep slope of a mountain, thus affording a fine natural facility for working the mine. Five tunnele on the line of the lead, about equi-distant apart, constitute the development of the mine. Tunnel No. 1 pierces the mountain 600 feet, the end of the tunnel reaching in 438 feet below tunnel No. 5, or the upper tunnel. Tunnel No. 2 is run 325 feet; No. 3, 400 feet; No. 4, 350 feet, and No. 5, 125 feet—in the aggregate 1,700 feet of tunneling. The output of ore is about 22 tons per day, the amount which the 20-etamp mill cruehes. The quartz is taken to the mill on a tramway from tunnel No. 1. Ore chutes conduct the quartz from the upper tunnels to it. The company work 62 men in mine and mill, and Walter McDermott, general superintendent and assayer; D. C. Trent, mill superintendent; M. L. Talon, foreman of mine; Wm. Muth, secretary.

If the 40 etamps at Veetal and the 20 stamps at Belmont can support the number of stores, boarding-houses, saloons, etc., which are uow doing a good business at those places, to what point of prosperity will the Silver Creek district reach when all her mines are developed and mills built to work their ores?

Mammoth District.

A correspondent of the Inyo *Independent* writes from Mammoth, Mono county, as follows:

Business assumes average proportions and a steady gait, although there are not many men here, yet those who are here are constantly at work producing something, and therefore every man has money once a month. Mines, their ups and downs, are multitude iu this region, and aside from the Mammoth and Headlight, they have a few more downs than otherwise; and here allow me to state that until these mines pass from the hands of the present owners and manipulatore the town is a failure, for be it known that not a mine, with the exception of the Mammotb, Headlight and Monte Cristo, is operated or manipulated on anything like legitimate principles. Although there are many other mines here which prospect about as well as the last mentioned, yet the owners are men who would rather lose an eye than unhook one dollar for prospecting. The Mammoth mine, which is destined within the next twelve months to gain a world-wide fame, never looked better thau at present, and if the present efficient Superintendent, Mr. Hardy, remains at the helm, the euterprise is an inevitable success. The Headlight and Monte Cristo joint tunnel, which is also superintended hy Mr. Hardy, has an air compressor at its mouth, receiving its regular rations of compressed air and steel from the Burleigh and Ingersoll drills, and before old Sol's vernal rays assert their rights in this region, there will be a tunnel into Mineral hill from the weet side, a distance of 900 feet, cutting through the north end of the Crescent mine, and uniting the Headlight and Monte Cristo at their junction, and at a depth of about 800 feet from the croppings thereof.

THE INFLUENCE OF THE HEAT OF THE INTERIOR OF THE EARTH.—Dr. F. M. Stapf, in the *Revue Universelle des Mines*, proposes the following questions: 1. At what degree of temperature will underground work he rendered impossihle on physiological grounds? 2. At what depth of a tunnel helow the surface may the occurrence of such a temperature he expected? After consulting Prof. Duhois Reymond, aud instituting experiments at his recommendation in the St. Gothard tunnel, the conclusion is drawn that it is possihle to work for a short time at 60° C. in a dry atmosphere, but that, if the air is saturated with moisture, 40° C. is the limit. The author considers that the products of the explosion of dynamite in mines may include nitric acid and carhonic oxide. Particles of nitro-glycerine are also held in suspension in the smoke, and occasion headache, indigestion, and other distressing symptoms. The eecond question will he discussed in a continuation of this paper.

A COLORADO ENTERPRISE.—From the Denver *Tribune* we learn that an important enterprise has heen estahlished there to he known as "the Great Western mining agency and hureau of general and special information." It is conducted by General Frank Hall, formerly Governor of the Territory, and for thirteen years editor of the Central City *Mining Register*, and hy Prof. J. Alden Smith, State Geologist.

Traps for the Unwary.

Now and then in every rural neighborhood there is a man who tires of the round of labor on the farm, and having secured a few hundred, or a few thousand dollars surplus, decides to come to the city and try to get into some "little business," thinking thereby to live an easier and, perchance, a livelier life. In all cities there are classes of sharpers who live upon what they can make out of these small capitalists from the country. There are the coarse operators who rely upon garroting their victims and extracting their money at a jerk. There is another class which trusts to a little finer practice, and relies upon lures to games of chance, and there is still another class which approaches nearest to respectability, and they operate by acting as friends, who can secure just the "little business chance" which the new-comer desires. They advertise openings in all kinds of business, from beer saloons to book-stores, and from blacksmith shops to iron foundries. For a certain sum of money they can buy partnerships in such concerns for their patrons. They will sell *anything* you can name, and often before the purchaser gets much older, he learns that he has bought *nothing* at a very high price.

Such has been the experience of many rural investors in Eastern cities, and many are the accounts of robbed and swindled people recorded in the papers. We were not aware that such was also the character of some of the "agencies" which operate in this city; but if a writer in the Vallejo *Chronicle* speaks the truth, San Francisco is well furnished with traps to catch the man who wants to get into "some little business." This writer, who styles himself "A Victim," tells of going to an "agency" and inquiring about an advertised "opening" in a machine shop. Under the pilotage of the agent, he goes to examine the opening. "Victim" gives the following account of the visit:

> Arrived at a dilapidated building among the iron foundries in the southeastern part of the city, the victim is conducted into a "shop," where three or four men (hired for the occasion) are at work, steam up, and everything presenting a scene of bustle and activity. There is no denying the fact that it looks business like, and is easily calculated to impress any one with a sense of confidence. The "proprietor" (generally an uncouth-looking, illiterate mechanic, in collusion with the agent, of course,) presents himself, with sleeves rolled up, dirty, smoke-begrimed visage, and pants and overshirt shining with the oil and dust of the shop (the result, doubtless, of years of wear, but not by their present occupant), and is introduced by the swindler to the victim. The agent, by a series of winks and signs, conveys to the hard-working mechanic that this is a good bite, but says, "this gentleman has an idea of buying in with you and would like a little information." (I must here say this "business" had all been pre-arranged between the "mechanic" and the swindler, and it is only during certain hours in the day that victims must be brought to the shop, for coal is dear, and it is quite expensive to keep two or three large wheels going all day, particularly when victims are scarce.) The "swindler" now leaves the victim to the tender mercies of the "mechanic," who, in his ingenious manner, begins a story of his business and its fine prospects, and for the truth of his assertions, he will allow Mr. Victim to converse with the workmen. If Mr. V. is not very gullible he generally takes advantage of the offer, interviews the "soot-covered gentlemen" and finds the "mechanic's" statement verified in every essential. A dirty cash-book is shown, with totals invariably large on the debit side, which at once assures the victim of the profitableness of the business. This book has been prepared for the occasion and the entries are false. A dingy order book, also prepared, lies beside it, in which a multiplicity of hastily-written orders have been entered, the chirography purposely made almost indistinguishable, so as to give a sort of "rough-and-tumble honesty" to it. Every device which a rascally brain can conceive is brought to bear upon the victim, who, after apparently satisfying himself that everything is as represented, pays his money, partnership papers in due form are drawn up and signed, and Mr. Victim is now a full-fledged partner in the manufacturing firm of "Mechanic, Victim & Co."
>
> But a few days elapse before the victim discovers the business suddenly dwindle, and the worthless nature of the whole thing appears by degrees, the victim leaves in disgust, and Mr. Mechanic is once more in possession. As soon as he is effectually rid of his victim, he returns to his agent, who places another advertisement in the paper, and the operation is repeated. Sometimes the swindlers run across an obstinate customer, and to prevent exposure they compromise with him. But as a general thing they are successful in the "freeze-out" game.

We give this alleged experience of "Victim" at length in order that readers may see with what ingenuity and elaboration such snares for unwary people are laid. Although it is rather sad to reflect that suspicion must always play such a part in our thoughts, still in all matters of dealing with strangers, whose interest lies plainly in producing a good impression, it is well to exercise the closest scrutiny and seek indisputable proof of the truth of their representations. Those who are unused to city ways must be more on their guard against misrepresentations than those whom contact with many people gives standards of judging. Our advice to all our readers is to proceed with the utmost caution, and run the risk of appearing very stupid rather than seize, with what may appear like business-like celerity, bargains which are the snares arranged by unprincipled and designing men.

HEAVY SALE.—An important mining sale was consummated at Helena on Friday last, the Bonanza Chief and Comet being the properties transferred, and the Alta-Montana company being the purchasers. The consideration for the Bonanza Chief is stated to be $30,000, which amount was on Friday deposited to the credit of the selling parties at the First National bank of Helena. The price paid for the Comet, which is a silver mine, is not known, though $40,000 was deposited on account.—*Butte (Montana) Miner.*

DURING 1878 more than 17,000,000 pounds of pork were imported into Bremen from the United States.

Useful Information.

HINTS CONCERNING SAWS.—A saw just large enough to cut through a board will require less power than a saw larger, the number of teeth, speed and thickness being equal in each. The more teeth, the more power, provided the thickness, speed and feed are equal. There is, however, a limit, or a point where a few teeth will not answer the place of a large number. The thinner the saw, the more teeth will be required to carry an equal amount of feed to each revolution of the saw, but always at the expense of power. When bench saws are used, and the sawing is done by a gauge, the lumber is often inclined to clatter and raise up the back of the saw, when pushed hard. The reason is that the back half of the saw, having an upward motion, has a tendency to lift and raise the piece being sawn, especially when it springs and pinches on the saw, or crowds between the saw and the gauge, while the cut at the front of the saw has the opposite tendency of holding that part of the piece down. The hook or pitch of a saw-tooth should be on a line from one-quarter to one-fifth the diameter of the saw; a one-quarter pitch is mostly used for hard, and a one-fifth for softer timber. For very fine-toothed saws designed for heavy work, such as sawing shingles, etc., even from soft wood, one-quarter pitch is best.

IRON AND GLUE IN STREET DUST.—In this country we have assays of street dust yielding gold in some towns, but glue and iron we have not searched for. Signor Parnetti has been engaged in analyzing the dust and *debris* of the streets of Florence and Paris. His investigation of the *debris* of the horse paths proves that the dust contains 35% of iron, given by the shoes of the horses to the stones. In the dust from the causeways this eminent chemist finds from 30% to 40% of good glue. Signor Parnetti selected and treated separately the dust from the causeways of the Boulevard des Italiens over a period of two months, which uniformly gave 30% of good transparent glue, it is said quite equal to Belfast. This eminent chemist is now engaged in the analysis of the dust and *debris* deposited by the shoe abrasions in Lombard street, Cornhill, Cheapside, and other thoroughfares of London, and has it in contemplation to place his discoveries at the disposal of a limited company, with a view of establishing blast furnaces on the banks of the Thames to recover the iron thus lost, and a large glue works, which, it is thought will produce more glue from the wasted material than will supply all London for every purpose.

VEGETABLE FIBER VS. HAIR FOR MORTAR.—Vegetable fiber is now successfully substituted, it is said, for hair in the composition of plaster for building purposes. The advantages claimed for it are as follows: First, being of a woody nature, instead of being destroyed when put in the lime, it is preserved, lime being a preserver of wood; second, it is light and bulky, so that one pound, costing but a small sum, is sufficient for a barrel of browning, and two pounds for a barrel of lime scratch coat; third, it is much stronger than hair, is very light, clean and entirely free from foreign substances; fourth, it mixes more easily and freely with the plaster than is the case with hair, and also spreads more uniformly through the same. This being the case, the new fiber is greatly superior to the ordinary animal hair, the latter, as is well known, usually containing some 30% of its weight in impurities—as lime and scrapings of hides—while the hair itself, by the caustic action of the quick-lime used in removing it from the hides, loses much of its original strength.

SOME German and Russian rail mills employ an ingenious method to overcome difficulty in cutting red or nearly white-hot rails, so that they may be all the same length when cold. The rails are looked at through a dark glass; when they have cooled to a certain temperature they cannot be perceived. If a dark blue or an orange-yellow glass is used, the rails may still be at a red glow, but the light radiated from them does not reach the eye. It may be considered that the light from two rails observed through the same dark glass disappears at the same temperature, and thus a rule is obtained for cutting the rails to the same gauge. Each rail is allowed to cool till it can no longer be seen through the dark glass, and is then cut. The result is said to be satisfactory.

TO PROTECT IRON FROM RUST.—Iron can be protected from rust and made very pleasing in color by a method invented by Mr. Dode. He coats the surface with a thin film of borate of lead, in which some oxide of copper has been dissolved, and some scales of platinum held in suspension, by means of a brush or bath. He then heats the composition until it is diffused. The result is a thin, glassy coating, which will withstand the action of sewer gases, dilute acids or alkalies, and the heat of kitchen fire. If all he true that is said of this "platinized iron," as it is called, it will find numerous applications. —*Rev. of Sci. and Ind.*

ENGLISH manufacturers, it is said, have succeeded in producing a new cloth from the hair of the vicuna or South American lama. The cloth is called camelina vicuna. It is made in all the new colors, and also in ivory, but the latter hue is different from all other white goods, in consequence of the introduction of the black hairs that appear in vicuna wool.

THE STRENGTH OF WHEELS.—"I wonder," said a veteran wheelwright, the other day, "how many who see sleader wheels flying over the road stones, or a massive wheel slowly drawing a mass of iron or stone along the cobbles stones, ever pause to think what a perfect piece of mechanism a wheel must be to stand such continuous wear and tear. Every spoke must have a perfect bearing, both at the hub and on the felloe, lie exactly on the same plane as the others, and be of equally well-seasoned timber. The felloes must be an equally good fit at the joints and upon the spokes. They must form at the circumference a perfect circle, and be strong enough for their duty without being too heavy. I tell you that a ton weight continually thumping at a wheel will soon flatten out the weak spots, and bad-fitting and insufficiently-seasoned timber will soon give a loose tire, boys."

THE ANTIQUITY OF FORKS.—The proverb that fingers were made before forks used to be sometimes quoted in connection with the alleged very modern origin of that useful implement. But forks, if not so old as fingers, are now ascertained to date a long way back—as far as the prehistoric era of our race. They have lately been found, formed of bone, and evidently for table use, in the *debris* from ancient lake dwellings, while spoons, which for many purposes forks have superseded, are of still greater antiquity.

GUN barrels of superior quality are made out of the stub iron obtained from old horse-shoe nails. The stubs, after having been freed from all rust and dirt by being brightened in a tumbling-box, are combined with from 12% to 50% of steel in blocks of the same size as the stubs. The combined metals are puddled, hammered, heated, tilted and rolled into ribbons, to be wound in coils around mandrels, heated to a welding heat, and finished by a hammer on the anvil.

Good Health.

Poisons and Their Antidotes.

Reliable statistics, running for many years, and extending over large areas, show that accidents from poisons are of much more frequent occurrence now than formerly. This fact is no doubt due to the much more general use of poisons at present than in years past, both in ordinary household matters and in the arts.

While in all cases of poisoning the chief reliance must be placed upon medical aid, yet it often occurs that the need for a remedy is urgent, so that others should know the most ready and available methods of relief. There are some general instructions which, in the absence of direct antidotes, will apply to most poisons, and the New York *Independent* has done a good work in preparing and publishing the following quite full directions of how to act in cases of emergency, or while waiting for a physician:

Many poisons do their harm by their immediate action upon the esophagus and the coats of the stomach. Hence, if any liquid or soft solid substance is soon swallowed, it tends to diminish the effect. To this end liquids, such as water or milk, may be freely given. Oils also have a protective agency, and these diminish the virulence, especially of the acrid poisons.

It is also a safe indication to remove from the stomach by means of emetics the substance which has been swallowed. A teaspoonful of mustard in a tea-cup of warm water is generally nearest at hand, and may be given to an adult, or half the quantity to a child, every ten minutes until vomiting is excited. A half teaspoonful of powdered ipecac, given in the same way, will act as well. Tickling the throat with a finger or a feather five minutes after the emetic has been given, is likely to hasten its effect. They may well be aided in their action, as well as the stomach protected, by the use of flaxseed, or slippery-elm tea, or eggs, or jelly, or a teaspoonful of melted butter, or lard, or molasses. Whenever the poison is one producing stupor, cold to the head, warmth to the extremities, rubbing the skin with a flesh-brush, and attempts to rouse the person by alternate warm and cold sprinklings may be tried.

Better than all, the chemical antidote should be given, if known. Where an acid has been swallowed, soda, saleratus, lime, magnesia, or prepared chalk should be mixed with water and given in frequent doses. Of these the best is the calcined magnesia, given freely. If an alkali has been swallowed, as a lump of potash or lime, then acids, as vinegar, cider, lemon-juice, and the like, are indicated; but the use of oily and mucilaginous drinks must not be omitted. In poisoning with copper and its compounds, vinegar must be carefully avoided. The recent cases of pie-poisoning in New York city were probably owing to the action of some acid upon a copper kettle, or on copper in some other form.

Oxalic acid, used for cleaning metals, is sometimes taken by mistake for Epsom salts. Chalk, whiting, or other alkali should be freely used before any attempt to excite vomiting.

Prussic acid, although called an acid, is feebly so, and kills by its direct poisonous power over the nerves of organic life. The concentrated juice of peach leaves and kernels, of laurel, etc., may affect in the same way. Hartshorn, alternate cold and warm effusive stimulants to the surface and internally are more important than any other means. Artificial respiration, the same as directed for drowned persons, may be required. Smith's antidote of a half teaspoonful of pearlash, followed by 10 grains of copperas in water, is of service where you are sure as to the acid having been taken.

Sugar of lead and other salts of lead are best neutralized by white of eggs, Epsom salts, and lemonade.

When blue vitriol, or verdigris, has been taken, white of eggs, paste of wheat flour and flaxseed tea, sweetened with sugar, are indicated.

When green or white vitriol, or litharge, or yellow ocher have been swallowed, chalk and flaxseed tea are of service. If lunar caustic has been swallowed, a cupful of salt and water is the antidote.

Phosphorus, as used for poison of vermin and for matches, is sometimes eaten by children. Magnesia or other alkali, with water or mucilaginous drinks, are the readiest means of relief.

Creosote or an overdose of carbolic acid is to be met by white of eggs, milk and wheat-flour paste.

For poisons of the narcotic kind, such as opium, aconite, belladonna, henbane, digitalis and tobacco, there is not at hand any antidote. Stimulating emetics, stimulants to the surface, and, if need be, artificial respiration are indicated. Heavy draughts of strong coffee help to postpone the narcotism of opium. Lemonade or other mild acids are deemed of some service.

Overdoses of camphor or chloroform are an indication for alcoholic stimulants. We are still without certain antidotes for several of the narcotics.

Arsenic, either in its metallic form as gray fly-powder or the white arsenious acid, has an antidote in the hydrated peroxide of iron. Until this can be secured, warm water, milk, plenty of eggs, and lime water must be our reliance. The most frequent mistake of vegetable foods are the substitution of other varieties for the edible mushroom and the use of poke root (*Phytolacca decandra*) for horse-radish. No antidotes are known. But the indication is to use mustard or other stimulating emetics, and prevent further trouble by a few drops of laudanum, frequently repeated, until pain or sickness abates.

These are merely directions for those sudden cases of emergency which may occur in any family, and which, in the country, at least, occur when the physician is not within ready reach. With the use of disinfectants, insect remedies, Paris green (arsenic), and with the increasing familiarity of the people with various chemicals, public health requires great care as to labeling all such articles. The medicines left over from physicians' prescriptions should either be marked or thrown away. Teach those under your control not to eat any vegetable or leaf without knowing what it is. All flowers with the cups turned downward or hooded, and all stalks which exude a milk-white juice when broken, are to be regarded as poisonous. All paints, whether of oil or water colors, should not be held in the mouth. It behooves all householders to have a special place for keeping all extra hazardous or doubtful compounds, and to cast away all unmarked or unneeded bottles and packages.

DISINFECTANTS. — The National Board of Health, in its circular on "Disinfectants and How to Use Them," makes a clear distinction between disinfectants and deodorizers, and disseminates the wholesome truth that "disinfection can not compensate for want of cleanliness or of ventilation." The recommendations of the board as to the disinfectants to be employed are as follows: For fumigation (that is, the purification of an infected atmosphere), roll-sulphur; for sewers, cess-pools, and the like, sulphate of iron (copperas), dissolved in water in the proportion of 1½ pounds to the gallon; for clothing, bed-linen, etc., sulphate of zinc and common salt in the proportion of 4 ounces sulphate and 2 ounces salt to the gallon. The interaction of these two compounds doubtless results more or less promptly in the formation of sulphate of sodium and chloride of zinc, which last is recognized as being the most energetic of the mineral disinfectants. The recommendation of the board to employ the zinc compound in the form of sulphate (with salt), instead of applying the chloride of zinc directly, may perhaps be explained on the ground that the sulphate of zinc is a stable salt that remains in solid form, and may be exposed to the atmosphere without change; whereas the chloride of zinc can not be preserved in solid form save in hermetically-sealed vessels, having such a powerful avidity for moisture that it rapidly liquefies by abstraction of moisture from the air. This property renders zinc chloride inconvenient to handle. By its indirect production after the recipe of the board, this objection is overcome. The board does not recommend carbolic acid for general use, for the reasons that the quality of the commercial article varies greatly, that it is difficult to determine its quality, that it must be used in comparatively large quantity to be serviceable, and that it is liable, by its strong odor, to give a false sense of security.

THE *Chemiker Zeitung* is authority for the announcement that the German Imperial Department of Public Health is about instituting measures for the repression of secret and proprietary remedies; and that in Switzerland the sale of patent and secret medicines is about to be submitted to very stringent regulations.

MINING AND SCIENTIFIC PRESS

Our latest forms go to press on Thursday evening

SAN FRANCISCO:
Saturday Morning, Jan. 3, 1880.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Mining Companies Should Hold Reserves; Woolford's Improved Wrench; Quantity of Water in Mines; The Baldwin Locomotives; Mining Stock on the Eastern Boards, 1. The Week; The Bullion Yield of 1879; The State Legislature; Proportionate Wages in Mining; The Railway Disaster; A New Volume; Fraudulent Entry of Mineral Land, 8. An Improved Cam for Quartz Mills; Nobility of Labor; Dividend Paying Mines, 9. Notices of Recent Patents, 13.

ILLUSTRATIONS.—Baldwin Locomotive Co.'s Locomotive; Woolford's Improved Ratchet Wrench, 1. Moore & Dykes' Improved Cam for Quartz Mills, 9.

CORRESPONDENCE.—Refining Gold and Silver Amalgam; Refining of Gold and Silver Amalgam; Rainfall at New Almaden, California, 2. The Control of the Comstock Mines, 9.

MECHANICAL PROGRESS.—Some Hints About the Treatment of Steel; A New Pegging Machine; Corrosion of Boilers by Fatty Matters; Utilization of Steel Scrap; A Novel Motor, 3.

SCIENTIFIC PROGRESS.—A Horological Bureau; The Practical Use of Science; The Immensity of the Stars; Producing Alcohol by Electricity; A New Antiseptic; Carbon in Comets, 3.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, Oregon, Utah and Washington Ter., 4-12.

MINING STOCK MARKET.—Sales at the San Francisco, California and Pacific Stock Boards, Notices of Assessments, Meetings and Dividends, 4.

USEFUL INFORMATION.—Hints Concerning Saws; Iron and Glue in Street Dust; Vegetable Fiber vs. Hair for Mortar; To Protect Iron from Rust; The Strength of Wheels; The Antiquity of Forks, 7.

GOOD HEALTH.—Poisons and Their Antidotes; Disinfectants, 7.

NEWS IN BRIEF on page 12 and other pages.

MISCELLANEOUS.—The Gphir; A "Distillation Process" of Working Ores; Softening Argentiferous and Auriferous Lead; Explosion in a Gravel Mine, 2. A Profitable Gold Mine; The Gold Section of Montana; Mammoth District; The Influence of the Heat of the Interior of the Earth, 6. Traps for the Unwary, 7.

Business Announcements.

Locomotives, Cars, Etc., Williams, Dimond & Co., S. F.
Dividend Notice—S. F. Savings Union.
Dividend Notice—German Savings and Loan Society.
The "California Architect and Building Review," S. F.
"Scientific News," S. H. Wales & Son, N. Y.
Annual Meeting—Gila S. M. Co.
Annual Meeting—Con. Virginia M. Co.

The Week.

To us, the event of the week is the commencement of a new volume of the MINING AND SCIENTIFIC PRESS. We begin to-day—Number 1, Volume XL.—a volume which we propose shall *excel* all previous ones. In view of our age we may be pardoned the pun, especially as we shall not have another chance to make this particular one.

The coldness of the weather continues to be the uppermost topic. The cold spell has been the most severe ever experienced in this immediate vicinity. Heavy frosts and ice are unusual accompaniments of San Francisco winters, although in the interior of the State in the mountains they are common enough. Localities not heretofore visited have, however, had their share this time.

The ice and snow has had the effect of retarding mining operations materially, especially in that class of mines which depend on water. The hydraulic and placer claims are for the time shut down, or rather frozen up, and work has had to be suspended. Many quartz mining operations have also had work delayed.

The terrible disaster to the railway train while crossing the Frith of Tay in Scotland by which many lives were lost, forcibly calls the attention of the public to the question of construction of iron bridges. This bridge, considered a marvel of strength, has fallen within two years of its completion, and hurled to destruction a train full of people. So disastrous an accident has not occurred for a long time.

Before this issue of the PRESS reaches its readers, the New Year will have commenced, and although it may be somewhat late, our wishes to each and all a Happy New Year, will be none the less hearty.

A NUMBER of miners left Seattle this week for the Skagit gold mines, including several direct from Leadville, Colorado.

The Bullion Yield of 1879.

Seventy-three Millions for the Year.

We are indebted to Mr. John J. Valentine for an advance copy of Wells, Fargo & Co.'s circular concerning the bullion yield of 1879, from which we make the following extracts.

The annual statement shows the amount of precious metals produced in the States and Territories west of the Missouri river, including British Columbia (and receipts in San Francisco by express from the west coast of Mexico) during 1879, which shows aggregate products as follows: Gold, $32,539,920; silver, $38,623,812; lead, $4,185,769. Total gross result, $75,349,501; being less by $5,805,121 than for 1878.

The statement is as follows:

California	$18,190,973
Nevada	21,999,714
Oregon	1,037,981
Washington	85,336
Idaho	2,091,300
Montana	3,629,020
Utah	5,468,879
Colorado	14,413,515
New Mexico	6 2,800
Arizona	1,942,403
Dakota	3,203,387
Mexico (West Coast)	1,633,871
British Columbia	976,742
Total	$75,349,501

California shows a decrease in gold of $140,342, and in silver of $589,146—a net decrease of $729,488. Nevada shows a total falling off of $13,184,235, the yield from the Comstock being only $8,830,562, as against $24,295,043 for 1878—a decrease of $12,464,481 from that locality. The product of Eureka district is $5,859,261, as against $6,981,406 for 1878—a decrease of $1,122,145. Utah shows a falling off of $595,734. Colorado shows an increase of over $8,000,000, chiefly from Leadville district. It has been exceedingly difficult to arrive at the actual production of Leadville, the two most reliable reports varying more than $2,000,000. We have adopted an average based upon the conflicting figures. Dakota shows an increase of $993,183.

The bullion from the Comstock Lode contains 41 20-100% gold, and 58 80-100% silver. Of the so-called base bullion from Nevada, 27% was gold, and of the whole product of the State, 27 50-100% was gold.

The gross yield for 1879, shown above, segregated, is approximately as follows:

Gold	43 20-100%	$32,539,920
Silver	50 25-100%	38,623,812
Lead	5 55-100%	4,185,769
Total		$75,349,501

The outlook for 1880 does not indicate a greater product than for 1879.

Annual products of lead, silver and gold in the States and Territories west of the Missouri river, 1870-79:

Year.	Products as per W. F. & Co.'s statements, including amounts British Columbia and West Coast of Mexico.	Products after deducting amounts from British Columbia and West Coast of Mexico.
1870	$54,000,000	$52,150,000
1871	58,284,000	55,784,000
1872	62,236,959	60,351,824
1873	72,258,633	70,139,860
1874	74,401,145	71,965,610
1875	80,833,057	76,703,433
1876	90,875,173	87,219,859
1877	98,421,754	95,811,582
1878	81,154,622	78,276,167
1879	75,349,501	72,683,868

The net product of the States and Territories west of the Missouri river, exclusive of British Columbia and the west coast of Mexico, divided, is as follows:

	Lead.	Silver.	Gold.
1870	$1,080,000	$17,320,000	$33,750,000
1871	2,100,000	19,296,000	34,358,000
1872	2,250,000	13,924,429	38,177,395
1873	3,450,000	27,483,302	39,206,558
1874	3,800,000	29,699,122	38,466,488
1875	5,100,000	31,636,233	39,968,194
1876	5,040,000	39,292,924	42,836,935
1877	5,085,250	45,846,109	44,880,223
1878	3,452,000	37,248,137	37,576,030
1879	4,185,769	37,032,857	31,470,262

The exports of silver during the present year to Japan, China, India, the Straits, etc., have been as follows: From Southampton, $33,000,000; Marseilles and Venice, $5,000,000; San Francisco, $8,000,000. Total, $46,000,000, as against $39,000,000 from the same places in 1878.

The State Legislature.

We give on another page of this issue the names of the executive, judiciary and legislative officers of California who in a few days will take the reins of the State Government in their hands. After the careful sifting of candidates and character during the recent exciting political campaign, it seems as if those selected ought to prove faithful to their trusts.

Under the workings of the new Constitution of the State, the details of which these gentlemen are expected to see properly carried out, doubtless many perplexing questions will arise. Indeed they have no easy task before them in this alone, and the coming session of the Legislature will be a very important one.

In all those questions touching the welfare of the industrial classes of the State, particularly miners and mechanics whose ally we have been so many years, we propose a free discussion. Those of our readers who have the interests of their class at heart will be perfectly welcome to the use of our columns in discussing any questions which may arise affecting them.

Whatever measures may be proposed before the Legislature affecting the interests we represent, we shall promptly report to our readers and comment on freely. The expressions of our correspondents on these measures will without doubt be of value to the members of the Legislature who are in favor of general advancement rather than that of individuals.

Proportionate Wages in Mining.

The Scotch mine owners are mooting the feasibility of adopting a sliding scale of wages to their employees, to be based upon the market value of the products of the mines. As the prosperity of the owners is dependent upon the price of those products, over which they have no control, and as the permanency of the work of the miners is dependent upon the profitable returns from the mine to the owners, it follows as a natural sequence that when prices are low the wages of the men should contract in the same ratio; and to have an equitable hearing to both parties, when the prices advance the wages should also appreciate.

The chief difficulty in the way appears to be in arriving at a just and equitable root-basis, as the initial point of the scale. In the coal and iron mines a certain grade of the former, and a certain class of iron, might from their medium position in the trade be taken as the zero of price in the adjustment. In copper or lead mining the ingot, or pig of pure metal, would be the only positive form in which the market value would or could be based. There would be no other or medium grade which would allow of an average starting point being placed upon it. The fluctuations are from one point only. Copper, for instance, has within the last six months advanced over 40% in price; the fluctuations in lead and silver have not been as great, though they have been sufficient to warrant a marked difference in the profits of their respective mines. The owners of the copper mines, under the advance in copper, could well afford to increase the wages of the miners, if their ores were all uniform in value. But where the ores vary, as in copper, from 5% to over 60% of metal, the question becomes more complicated, and the equity is harder to be met.

If a fair starting point could be fixed, the advantages to the employers and employees would be better than they now are under the arbitrary and set prices for mining labor. The employers would not be subjected to the demands above a profitable rate to themselves by the workmen, when there should be an undue supply of labor. They would be able in all cases to meet a decline in the market prices, knowing that a proportionate decrease in the cost of production would be attendant upon it. This system would be the exterminator of the greatest evil incident to the labor problem, as it would remove all cause of strikes by the workingmen.

The employees would derive the advantage of a rise in the market price; they would not be subjected to the depression in the rate of wages arising from an over-supply of labor; nor would they be liable, as they now are, to be turned out of employment by the fall in the market of the price of the metal they were turning out.

It would operate to the mutual advantage of each, inasmuch as it would create a better and more harmonious feeling between both, than can possibly exist under the present arrangement. It would establish an identity of interest between them, and being founded upon justice and equal rights, it could not fail being successful.

The fewer obstructions or incumbrances that are inflicted upon mining operations, the better it will be for all parties in the transaction of the enterprise. Under this view this question of proportionate wages will have to be very long given a due amount of consideration.

The Railway Disaster.

The whole country was shocked this week on hearing of the terrible disaster which occurred at the Tay bridge, in Scotland, where many lives were lost. How many is not definitely determined. During a very heavy gale or hurricane the train in crossing was precipitated for eighty-eight feet into the river. Whether the central portion of the bridge had fallen before the train arrived, or whether the super-added weight of the train caused the breakage of the bridge, is a matter of conjecture. No one was saved to tell the details.

The Tay bridge is the largest iron bridge in the world and has been considered one of the most important engineering works in England. It crossed the Frith of Tay, and was 10,320 feet long. The bridge comprised 89 spans, 14 of the spans, over the navigable portion of the river, being 200 feet each and giving a clear headway of 88 feet above high water. It was at this point that the bridge gave way.

The magnitude of the bridge, and the novelty and ingenuity of the means employed in its erection, gave it rank with the most interesting civil engineering works ever carried to completion. This disaster, however, will call more direct attention to the details of its construction, the defects of which will now have to be carefully studied. Another large bridge of the same general character is now in course of construction, but it is highly probable work on this will be discontinued, pending investigation of the defects of the other.

The accident will tend to call the attention of engineers all over the country to the problems of railway bridge construction, a question in which the public is directly interested. We shall, next week, give the details of construction of this bridge more fully.

A New Volume.

The head lines of the PRESS for this week are changed to "No. 1, Vol. XL." In so young a country as this is, comparatively, a newspaper which has reached its fortieth volume is quite an old one. Indeed, in the particular field which the PRESS fills, it is the oldest paper on the coast. The first number of this journal was issued in May, 1860, and it has ever since been devoted to science, art, manufactures, mining and inventions.

With the increased attention now being paid to the mining interests of the United States, and especially those on this coast, the mining industry will undoubtedly have its importance more generally recognized. We shall continue to furnish such information to our readers concerning mining and metallurgical operations and improvements as will be useful to them, and this increased activity will enable us to do even more than heretofore.

There are no miners or mechanics on this coast who can afford to be without the PRESS as a weekly visitor to their cabins or shops. We hope, therefore, with the better times now dawning upon us that all those who are able will assist us with their subscription. We are always glad moreover, to receive correspondence and suggestions from practical men, and hope our readers will remember us in this respect also.

We intend this year to make many improvements in the PRESS. We have in contemplation several series of articles connected with metallurgical operations, which will be written by gentlemen of practical experience in their particular lines. These, with others we have in preparation, will make up more than usually interesting numbers, which will be useful for reference to all interested in mining or metallurgical operations.

Fraudulent Entry of Mineral Lands.

Some time last August a petition was sent from Auburn, Placer county, in this State, signed by a number of miners, to the Secretary of the Interior, reciting that it had been and is the practice of a certain class, to claim land as agricultural, and conceal from the land officers its mineral character, obtain title, and then sell and hand the same to be worked for minerals. It also referred to the Central Pacific Railroad Company as being in the practice of issuing citations for hearings to disprove the *prima facia* mineral character of odd sections within its grant, and, at the hearing abandoning such portions as are claimed by miners as minerals, and after a few months again citing the miners to another hearing concerning the same land. The petition asked that when land is once determined or conceded to be mineral, it shall forever be deemed and held as such.

The Acting Commissioner of the General Land Office has sent the following answer, which is published in *Copp's Land Owner*:

"In the matter of fraudulent proceedings under agricultural claims, to obtain title to mineral lands, it is obvious that no broad and unqualified rule can arbitrarily be enforced which will be effective under the present laws. Land which is in fact non-mineral is subject to agricultural entry, and if a party seeks under such entry to obtain title to a mineral tract, it is the duty of miners and others who may know its true character to appear at the district Land Office *and submit proof thereof*. The knowledge of the character of any certain tract is local, and this Office must necessarily depend upon parties in the vicinity to prevent fraud in said respect. Published notice of 30 days is uniformly required of parties who seek agricultural entry on lands withdrawn as mineral, and thereby all parties are advised and furnished opportunity to defeat any fraudulent entry.

"In regard to the alleged proceedings of said railroad company, you are advised that when a hearing is had to determine the character of certain lands, those alleging them to be valuable for mineral should *submit their proof at the hearing*, and thereafter this Office would be in a position to conclude the respective claims of all parties. But if you neglect to submit your proof, and the said company presents none, it is plain that this Office can render no final decision, nor can I anticipate any particular excuse which may be urged for the neglect.

"In short, if under the present laws those interested in preventing fraudulent entries of mineral lands will avail themselves of the means now furnished them by existing regulations, and appear and *insist* upon the right to submit their testimony at the hearings referred to above, and notify this Office forthwith of any refusal to receive their testimony, or irregularity of proceedings, a just conclusion can be usually reached; but without the co-operation of those interested in an honest disposition of the public lands, it is apparent that this Office labors under great embarrassments.

"You are assured that it is the desire of this Office and Department to be advised *by affidavit* of attempted fraud in any case; but it is clearly impracticable to act upon general allegations referring to no particular claim and tract."

THE dividends of mining companies, having their headquarters in San Francisco, for the year 1879 aggregated $6,678,000, over $11,000,000 less than last year.

An Improved Cam for Quartz Mills.

We illustrate herewith an improved cam for quartz mills, recently patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Lewis A. Moore and John Dykes, of Oresna, Humboldt county, Nev. The improvements in the cam consist in forming a removable shoe or face attached to the body of the cam by means of bolts, and placing between said body and shoe a cushion or packing of any elastic substance that will yield or spring under the blow of the cam on the tappet, so as to reduce the jar attendant on the sudden contact.

In Fig. 1 the body of the cam, *A*, is shown in double form as usually applied to quartz mills. A hole is formed through the center through which the cam shaft passes, the cam being keyed to said shaft in the usual manner. The body of the cam and also the shoe, *B*, may be constructed of steel, iron, or any other metal adequate to the requirements. Between the shoe and body of the cam is adjusted a strip or cushion, a, of any required thickness, composed of vulcanite rubber, or any other suitable elastic substance that will yield or spring under the blow of the cam on the tappet. The joint surfaces between the body of the cam and of the shoe are made to correspond one with the other as shown, so that a perfect joint is effected between the body of the cam and the shoe when the cushion or packing is put in place. The whole is then bolted or secured firmly together with bolts or studs, *D*, running transversely through the body of the cam from the lower edge to and into or through the shoe, *B*, fitting rather loosely without threads through the cam body, *A*, but tapped and screwed into the shoe, bringing the shoe, *B*, firmly down on the cushion and cam body. The joint surfaces between the body and shoe may be plain or corrugated, or the shoe may have a bulb at one end as shown at *C*, or he made in any desired shape, so that the joint surfaces correspond one with the other, admitting the cushion between, and not altering the proper angle of the face of the cam. Fig. 2 shows the cam with shoe removed.

In this improved cushioned and shoed cam, when the shoes become worn they may he adjusted in a few moments without displacement of the body of the cam, thereby saving great time, labor and expense, as usually the cams have to he unkeyed and entirely removed from the cam shaft. In case the cam or shoe wears away in a bevelled shape the shoes can be changed from one arm of the cam to the other arm of the same cam, or to any of the other cams of the battery, and *vice versa*, thereby effecting equal wear on both the shoes and tappets.

The yielding capacity of the cushion effectually and completely obviates all violent or sudden blows, which are so destructive to the iron work of the battery, since under a cushioned blow crystallization of the iron does not occur, nor does looseness of cams and tappets, or chipping and breaking take place. Neither will the shoes or bosses be apt to drop from the stem, as is the case when a succession of sudden jarring blows is made with a solid cam. As the cam and tappet come together easily and smoothly, there will be no loss of power incident to drawing the stems against the guides of the battery.

Nobility of Labor.

It has long been a disgrace to the intelligence of the age, that a stigma should be attached to labor. It is the source of national and individual wealth. It is the primary cause of social comfort and convenience. It has raised man from the lower grade of an animal prowling for his food to the higher plane of an intellectual being, possessed of reason, thoughtfulness, foresight and inventive faculties. It has given man a clear insight into the laws of nature, and has brought him into close companionship with the Creator. It has made him a creator, not of matter, but of new forms of its adjustment. He has made the iron and the wood his docile slaves, and caused them to perform work which, without their aid, he could never have accomplished. By labor he has sunk his mines deep into the earth and extracted therefrom earth's most valuable treasures. By labor he has made the fields to yield abundant harvests, and gathered from them the world's supply of food. By labor he has built his ships, whose sails bear them to all portions of the world and sustain the mighty operations of commerce. By labor he has constructed railroads which traverse continents, and transport in their trains, not only multitudes of human beings but also the products of the mines, the fields, the factories and the workshops. By labor he has run his tunnels through mountains and under rivers, and rendered quickly accessible sections of country which else could only he reached by long and tedious journeys. By labor he has stretched around the world the wires of the telegraph, and has given thereby to himself the God-like attribute of omnipresence. By labor he has produced the telescope which has shown to him the vastness of the Creator's designs and works, in the millions of worlds that are placed throughout the realms of space. By labor he has analyzed the compound forms of matter, and has found the constituent elements of their composition. By labor he has closely emulated Deity, for God worked in the creation of all worlds, and in the production of all the living forms that are found upon them.

With such a record labor should stand in the highest niche of honor and of fame, and the man who is the most prominent in works of utility should reach the highest standard of nobility, and should he the most honored among his fellow-men. It is a false and ignoble pride that has engendered this prejudice against labor. It is the direct action of evil against positive good.

For all these benefits which it has conferred upon mankind, it should receive the gratitude of all. The pride that from its mole-hill eminence endeavors to look down with contempt upon labor, could never have attained its ephemeral existence or its insignificant elevation, had it not been for the labor performed by others. The most utile nobility among men is the self-sustaining nobility of labor.

Dividend-Paying Mines.

A Leadville (Col.) paper crows over a statement that in October, Leadville mines paid dividends amounting to $135,000, while dividends for California, Nevada and Black Hill mines aggregated during the same period $447,200; so the Leadville mines paid about one-third as much as all the dividend-payers of the West.

Now, if this was a fact, the Leadville journal might have cause for self-gratulation; but it is not a fact. The mistake is made of estimating the dividend-paying mines of the West, particularly of this State, by counting those only quoted on the stock boards. No greater mistake could be made. There are very few, proportionately, of the mines which are listed at all. In this State, particularly, not more than a dozen or so appear on the boards.

We don't recollect seeing a quotation of stock for a California hydraulic mine for several years; yet this class of mines produce over a million a month regularly. Many of them pay their owners handsomely. None of the stock is for sale, and the dividends are quietly pocketed without any newspaper heralding whatever.

Hundreds of quartz mines worked by private owners and private companies pay dividends regularly that the public knows nothing of. Yet in the new districts, like Leadville and the Black Hills, when a mine pays a dividend and there is a great fuss made over it, the fact being telegraphed all over the country.

The drift mines alone in this State produced over two millions of dollars last year; but there is not one Eastern man in a hundred knows even what a drift mine is or how it is worked, yet they have paid handsome dividends. Still not one of them is quoted on our board. The reason is apparent enough. The mines that pay regularly and are properly opened and developed do not need the stock board to assist them. Plenty of men are willing to own stock in such claims and keep it as a legitimate investment. That is not the sort which is "worked" by the hulls and bears.

Such mines, however, are not for sale to Eastern people or any others. The owners do not care about their doings being published abroad. We know of one little mine alone in this State, owned by three men, which is paying above expenses over $50,000 per month; yet if we should mention its name, very few would ever have heard it. There are many others on a smaller scale. We don't like to see *all* our mines take a "rating" from the few listed on the stock boards.

The Control of Comstock Mines.

[Written for the PRESS by J. D.]

Although the stocks of the Comstock mines are very much depressed, and people feeling poor on account thereof, yet the business of prospecting and development still goes on; and with the doubt of the future results of the prospecting hanging over the business, the assessments constantly levied, first on the stock of one mine then on another, continue to he paid. The Comstock stockholders have the nerve to submit as long as they have the means to respond to oft-repeated assessments, and they exhibit a degree of patient submission which is truely admirable. It may ho that as they have been so long accustomed to it, they have formed a habit which has become second nature. Often when the report has been circulated that a bonanza has been found in a mine, and that the extraction of ore would immediately commence, making the fortunate stockholder buoyant with the hope that he would soon be the recipient of large dividends, his hopes would be blasted by the announcement that there was an assessment levied on the stock, which of course would be the last one that would he levied, and he pays it, expecting to he receiving monthly dividends ever after. But, alas, another assessment is levied, and in due course of time another, and so on—the end thereof he knoweth not—notwithstanding the fact is reported that a bonanza exists in the mine. If the money collected by assessments was always honestly and judiciously expended in the development of mines where there was evidences that a mine existed, then there would he more satisfaction in paying them.

If a stockholder had the privilege at any time he choose of going into and examining the property which he is an owner in, so that he could judge for himself as to the prospect of developments of ore being made, and to see with his own eyes whether work was being intelligently and honestly done; and to see whether or not the parties having the management were managing for their own interest without regard to the interests of other stockholders or proprietors, then he would submit with better grace to repeated assessments if he found all things conducted in an intelligent and proper manner.

Why are parties so anxious to become managers of mining property, unless it is because they fear that other persons if they obtained control would not conduct matters for the best interests of all the stockholders; or is it that they want the opportunity to manage for *their own* individual interests and make money out of it, even if the other stockholders suffer by it? The general supposition is, that the managers conduct the business so that they will have an advantage over all other stockholders and make money, while others loose. They keep secret the exact condition of the mine, and report it in a better condition than it is; or do not let it he known until it suits them, when a body of ore is developed. They are on the inside, and profit by it. If ore is discovered and it is generally known, the stock would in consequence go up. That they do not want, until they have succeeded in depressing it as low as possible, and keep it there until they have bought up all they can, then, of course, the cat is let out of the bag, and they proceed to circulate reports, and inuendoes to hull the stock to a high figure, when they sell and make a very good thing out of the "deal."

They do not expect to enrich themselves from dividends, but on the rise of the stock in the market. This explains why persons are so anxious to become managers of mines. The Union Con. has run about 80 feet through ore of tolerably high grade. Now whether that is through the width of the ore body, or lengthwise, or diagonally, is not generally known on the outside. The exact condition in regard to the deposits of ore found in the Sierra Nevada is not known except to insiders. There may be more ore developed in the mine than the managers care to have known by the owners of the mine outside of themselves, or there may be less, which fact they keep concealed to delude the public, to keep the stock up. As to the Mexican, favorable indications, such as "bird's-eye porphyry," clay and streaks of "kindly"-looking quartz, to keep the stock up is about played out.

The sham arrangements entered into by the Bonanza firm and Hayward and his friends for control of the Hale & Norcross; also that with Graves and his friends for control of the Yellow Jacket, are pretty well understood. The same superintendents who officiated under the old management are retained by the new, and one of them is also made a trustee. This may have been done to convince people that Flood & Co. do not know of any bonanzas in either of those mines. But people will not he convinced. They are so full of disbelief that they think the Bonanza firm still have the secret management.

However that may be, it seemed strange to the public that Mr. Hayward and friends, and Graves and friends, should wish to get control of those mines. As the Bonanza firm own mills that are now idle, they have, I have no doubt, made arrangements with Hayward, Graves & Co., to let the ore from the Hale & Norcross and Yellow Jacket go to their mills as soon as they commence the extraction. It is quite an object for a company owning mills to he able to control the ore coming out of the mines. The reduction of ore they make quite profitable. All that comes out of the rock does not go to the mining companies, only a percentage of it. Neither do the slime and tailings. All these perquisites, with the price charged per ton for reducing, make the milling of ores quite profitable. It will he seen that it is quite an object to get control of one of our mines, for the reason that those having it control the manipulation of the stock, the reducing of the ore and furnishing supplies, and the outsiders have to pay the assessments, and submit to all of the requirements made on them without having a voice in the business, and not even allowed to know the condition of their property, or that in which they hold a large interest, but their authority over it is entirely ignored. I suppose that there is some profit attached to the control of the bullion, as well as other items mentioned above.

So, taking matters altogether, there is no wonder that there is strife to get control of mines. Those who have it make a good thing out of it when the shareholders make nothing, when there are no dividends.

Of course it is necessary that mining stocks should he assessed, to furnish the means for opening and developing mines, but then the money raised in that manner should he applied to carry out the objects for which it is raised. The managers should he intelligent business men as well as honest, and should employ superintendents and subordinates who are versed and skilled in the business which they undertake to perform. This is expected of mine managers; and if they do as they should, the business of mining would he looked upon in a different light from what it is now. It is a legitimate and important industry, unassociated with schemes of swindling and gambling. Work mines for what they are worth, not for the purpose of speculating on the stocks.

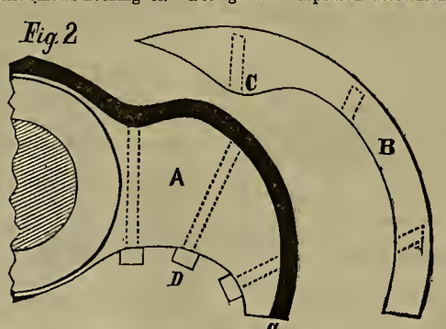

Fig. 2

CAM WITH SHOE REMOVED.

THE NOONDAY MILL.—The new 30-stamp mill of the Noonday mining company, at Bodie, was started up for the first time on Christmas day. This mill was built in San Francisco by Hinkley, Spiers & Hayes of the Fulton foundry. The Bodie *Standard* describes the Christmas start as follows: A lady visitor sounded the whistle for the start, and when the ponderous machinery moved of like the works of the most delicate watch, other lady visitors seized the whistle cord and made the welkin ring with a prolonged whistle. The visitors included members of the press, merchants, bankers and others, and all seemed as delighted with the fine success of the start as if they had been personally interested as builders. Mrs. John Parham, wife of the Superintendent of the Noonday mine and mill, presided in the engine room and did the honors by personally opening several baskets of champagne. Toasts were drank, but the noise of the heavy machinery was too great for any extended remarks in reply. The mill is situated near the mine, with a railroad track running from the hoisting works to the batteries for the transportation of ore. The hoisting works are of the most improved and powerful kind, and the mill is a model, and the smoothness with which it runs, and the efficiency with which it does its works reflects the highest credit upon all connected with its construction and operation.

THE coinage of the San Francisco Mint for the year 1879 was $38,065,750, of which $9,110,000 was in Standard Dollars, $24,476,000 in Double Eagles, $2,240,000 in Eagles, $2,131,000 in Half Eagles, and $108,750 in Quarter Eagles.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, $7.50

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working sample, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Krochnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, $2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

TO APPEAR SHORTLY.

Grimshaw on Saws.

History, Development and Action, Classification and Comparison, Manufacture, Care, and Use of Saws of all kinds. 8vo. Illustrated. By ROBERT GRIMSHAW.

This thorough little work, impartially written in a clear, simple and practical style, and supplemented by valuable tables, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small Hand, Sash, Mulay, Jig, Drag, Circular, Cylinder and Band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With Appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc.; tables of gauges and other valuable information. Elegantly printed on extra heavy paper. Subscription price, $1.50. Orders for first edition received now.

CLAXTON, REMSEN & HAFFELFINGER, Publishers,
624, 626, 628 Market St., Philadelphia.

Pocket Map of California and Nevada.

Compiled from the latest authentic sources, by Chas. Drayton Gibbs, C. E. This map comprises information obtained from the U. S. Coast and Land, Whitney's State Geological, and Railroad Surveys; and from the results of explorations made by R. S. Williamson, U. S. A., Henry Degroot, C. D. Gibbs and others. The scale is 18 miles to 1 inch. It gives the Judicial and U. S. Land Districts. It distinguishes the Townships and their subdivisions; the County Seats; The Military Posts; the Railroads built and proposed, and the limits of some of them; the occurrence of gold, silver, copper, quicksilver, tin, coal and oil. It has a section showing the hights of the principal mountains. The boundaries are clear and unmistakable, and the print good. 1878. Sold by DEWEY & CO. Price, postpaid, $2; to subscribers of this Journal, until further notice, $1.

507 Mechanical Movements.

Every mechanic should have a copy of Brown's 507 Mechanical Movements, illustrated and described. Inventors, model makers and amateur mechanics and students, will find the work valuable far beyond its cost. Sold by DEWEY & Co., Patent Agents and publishers of MINING AND SCIENTIFIC PRESS, San Francisco. Price, $1, (post paid.

The Explorers' and Assayers' Companion.

(THIRD EDITION.)

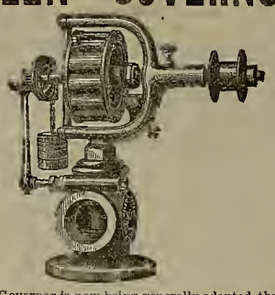
Coats of Arms, Crests, Monograms and Masonic Inscriptions Carefully Engraved.

ALLEN GOVERNOR.



This Governor is now being generally adopted throughout the United States and Europe. It is without doubt the

Most Perfect Engine Regulator in Use,

And will in most cases save its cost several times a year. It is invaluable on a QUARTZ, FLOUR or SAW MILL ENGINE, or in any Manufacturing Establishment, where Regularity of Speed is desirable. By being able to run the engine to its full capacity, these Governors have in many cases added

Ten Per Cent. to the Productive Capacity of a Mill,

Thus saving more than their cost every week in the month. Every Engine to which this Governor is attached will run with the throttle wide open. The speed of the Engine can be changed by a simple adjustment of the weights. It will give a UNIFORM SPEED WITHOUT REFERENCE TO THE BOILER PRESSURE. It is simple in construction and not liable to get out of order.

Every Governor warranted to give perfect satisfaction. Thirty days given for a trial, and if it does not fulfill all that is promised, it can be returned at our expense.

In ordering, state the kind of engine, diameter of cylinder, stroke, speed, and average pressure.

Send for full descriptive circular.

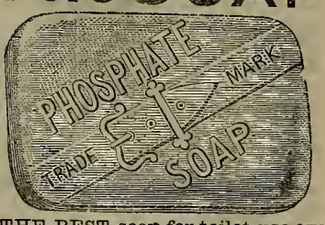
PHOSPHATE SOAP



THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detersive qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If you wish to make your hands soft buy a cake of PHOSPHATE SOAP, and when that is gone you will buy a dozen and recommend your friends to do the same.

Ladies who wish to make the skin look beautiful and natural should use PHOSPHATE SOAP.

For chapped hands the constant use of PHOSPHATE SOAP will be recommended by all who give it one fair trial.

TESTIMONIALS.

SAN JOSE, September 24, 1879.

To the Standard Soap Co.—Gentlemen:

It affords me pleasure to say to the public that I have used and prescribed your PHOSPHATE SOAP as a remedy in various forms of cutaneous diseases with the happiest results. I am of the opinion that it is the mildest and most perfect detergent that can be used, either for cleansing the skin and leaving it soft and healthy, or for removing the fetor and corroding influences of sores and ulcerations. I should be sorry to be without it in shaving my face or making my toilet, to say nothing of my good opinion of its remedial qualities.

A. J. SPENCER, M. D.

SAN FRANCISCO, Aug. 27, 1879.

Gentlemen:

I received a package of your soap (Phosphate Soap) and it gives me great pleasure to testify as to its superior excellence. As a toilet soap I have never seen anything to surpass it. It also possesses superior remedial qualities. I have used it in two cases of obstinate skin disease, one of intolerable itching, *Pruritus*, the other an *Eczema*. In both great relief was obtained. Its emollient properties are remarkable. Respectfully,

W. A. DOUGLASS, M. D.,
126 O'Farrell St.

To the Standard Soap Company.

SAN FRANCISCO, July 19, 1879.

Standard Soap Co.—Gents:

I have tried your PHOSPHATE SOAP, and have no hesitation in saying that it is the best toilet soap I ever used. My wife has used it and is of the same opinion. I have paid as high as fifty cents per cake for an article in every respect inferior to what you sell for twenty-five cents. HENRY H. LYNCH,
515 Haight street.

The genuine merits of PHOSPHATE SOAP and persistent advertising will force every druggist, groceryman and general dealer to order it by the gross sooner or later. Ask for it in every store. The retail price is 25 cents per cake. We wish to sell it only at wholesale, but in case you cannot find it we will send a nice box of three cakes by mail, postage paid, on receipt of 85 cents in stamps.

Ingersoll Rock Drills.

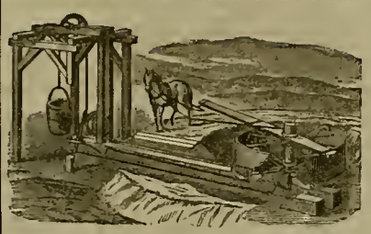
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



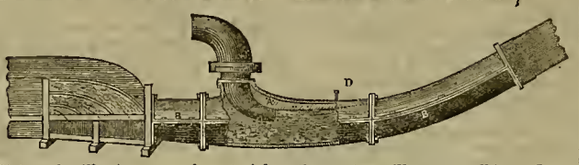
MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

HYDRAULIC GRAVEL ELEVATORS,



For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY,

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F

SECURE PATENTS

Through Dewey & Co.'s **Scientific Press** (Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventious patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the pateutability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., PATENT AGENTS.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

SHEET IRON PIPE.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

Sanderson Bros. & Co.'s

BEST REFINED CAST-STEEL.

WARRANTED MOST SUPERIOR FOR DRILLS, HAMMERS, ETC.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock, and for sale at

21 and 23 Fremont Street, S. F., - H. D. Morris, Agent.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by *letter.*

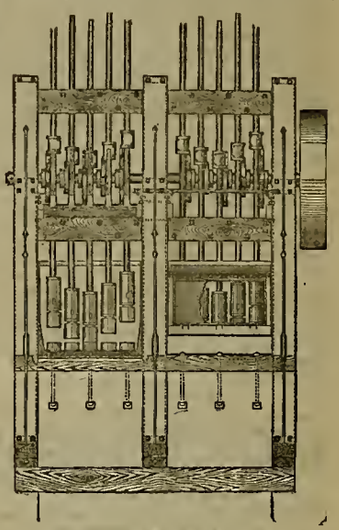
AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office

Machinery.

GOLD AND SILVER
Grinding and Amalgamating MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chlorodizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.



SPERRY'S
Wrought-Iron Frame
FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.

We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

$2,250.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

Mines and Works of Almaden.

Translated from "Annales des Mines"
BY S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (postpaid) 50 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

CONTINUED FROM PAGE 5.

known as Mineral Hill, 12 miles east of Florence, which are surprisingly rich. In the Finch mine, at the depth of 64 ft, a body of ore five ft wide was struck, which assays from $500 to $3,000 per ton in silver. Also in the Jonce & Nesbith mine, this same body of ors is found, but not quite so wide, though it also has a fine prospect. The diggings are on an iron-capped mountain which stands out by itself and is a general network of veins and ledges running in all directions, and which have always been thought nothing but iron. Finch was offered $50,000 in cash for his claim; and others had also good offers, but not so much as Finch, as his is far the best claim.

ITEMS.—The McCrackin mill is running on tailings. The Signal mill will start up Jan. 1st. The tunnel in the Eureka mine, Black hills, is in 270 ft. Masterson's mill, on Turkey creek, is running on Goodwin ore. The Peck mill starts up soon. Good ore is being taken from the 175 level of the Silver Prince mine. The Corbin mill, 15 stamps, in the Tombstone district, will be ready to start up Jan. 1st. Bob Groom has recently discovered a fine ledge on Castle creek which gives, by assay, $320 gold per ton and 40% copper. Mr. Worthington has located some valuable copper claims, and is perfecting arrangements for the erection of a custom mill, on Tule creek, near the Pearl mine, in a northeasterly direction from the Tiptop. Castle Dome has lately shipped 50 tons of ore. The Western mining company lately received 100 barrels of bluestone.

RICH STRIKE.—Tombstone *Weekly Nugget*, Dec. 25: A new and rich strike has been made on the south side of the Mule mountains, assaying between $7,000 and $8,000 per ton. This strike is in the joint shaft between the Champion and Green Horn claims, and is found at a depth of about eight ft. Foley & Co. own these claims, and their location is in the pass about two miles from Dyer's camp. In the same locality the Silver Rule has a shaft 18 ft deep, from which they are taking out ore assaying $125 in gold and $150 in silver. Globe claim gives about the same assay. It is thought these ledges are 20 to 40 ft wide, the walls not having been reached on either side. Mr. Fraser has a claim there which gives $4,880 to the ton in silver. Morgan & Hagin get from $400 to $1,200 from their ore. Dyer Bros. also have some fine claims. Placer miners are making $2 to $3 per day. Great many prospectors are now in the camp.

COLORADO.

MOUNTAIN CHIEF.—Silver Cliff *Prospector*, Dec. 22: This mine is located in Crees' camp, about eight miles from Marysville. Ore is packed down the mountain side, a distance of three miles, on burros, and from there wagoned to Silver Cliff, where it is sampled and then hauled to Canon, thence by rail to Omaha, Nebraska, where it is smelted. This mine, at a distance of only 30 ft, has more than paid expenses.

SALE OF A MINE.—The Denver City mine, near Leadville, has been sold to Philadelphia parties for $125,000. The new owners propose to stock the mine and place it on the Eastern markets at once. The shaft is down 430 ft.

SURPRISING ASSAY.—Fairplay *Flume*, Dec. 25: A very surprising result was obtained a few days since from rock taken out low down on Sacramento gulch. The drill had penetrated, in sinking, several feet of black sand. This was at a depth of not over 60 ft, and the sand was thought to be a part of the deep "slide" that covers the rock in place in this gulch. Out of curiosity the owners had the sand tested by the assayer at the Duquesne smelter. It returned a button that weighed up at the rate of over 360 ounces, or over $7,000 to the ton in gold. All the parties interested are incredulous over the result, and are drying more of the sand, preparatory to having several more tests made.

RUMORED LEASE.—It is rumored that Judge Bond has leased the Phillips mine to a company from Leadville. They have ample means and are compelled by the terms of the contract to have a first-class 20-stamp quartz mill in running order on the premises by the first of March next.

COAL MINING.—Six men, under the direction of E. J. Bowen, are opening the newly discovered vein on Lillenthal's ground with excellent success. The vein is widening as they go down, and although the coal is still soft, yet it is no more disintegrated than might be expected so near the surface. The four years' lease of this ground, which the company has secured on favorable terms, is worth considerable money. They have also leased from C. F. Ulmer his coal land near by, on which coal has been "proved up" in quantity long since. Members of the company have also located and claimed out-lying tracts of land near by. Work will be prosecuted on all of these, and systematically carried on until a sufficient amount of coal to operate extensive coke pits has been secured.

CLEAR CREEK ITEMS.—A good strike was made recently on the Baxter at a depth of 100 ft from the surface, consisting of a six-inch vein of ore, consisting largely of gray copper, and carrying native silver sprinkled through it. A run of ore from the Emma lode, on Democrat mountain, recently milled at the rate of 602¼ ounces of silver per ton without classifying.

IDAHO.

ATLANTA.—*Idaho World*, Dec. 23: The Yuba tunnel at Atlanta is progressing finely, and richer ore is being developed as depth is obtained on the mine. A sufficient ore body has already been developed to warrant the erection of an 80 or 100 stamp mill at the mouth of the tunnel. There is abundance of wood and water handy, and low grade ores can be worked with profit.

COAL DISCOVERY.—Boise City *Statesman*, Dec. 23: Mr. T. A. Mulford has discovered coal within three miles of Boise City. He has had large experience in the coal mines of Pennsylvania, and expresses himself satisfied that the vein he has discovered extends across and underlies most of the Boise and Lower Payette valleys, as the main formation crops out along the banks of these rivers. Overlying the vein there is a thick strata of slate, specimens of which he showed us. Mr. Mulford is making preparations for thoroughly prospecting his discovery.

MONTANA.

A GLACIER CLAIM.—Helena *Independent*, Dec. 18: The Montana mine, in the Yankee Fork country, was found in a real glacier. Sixty ft of the surface croppings had been broken off and carried some 30 or 40 ft down the mountain. The owners knowing the glaciers never move up hill, followed upward through the ice and frozen ground until they reached the point where the lode was broken off, finding it as large and quite as rich as below. The company's ore-house, dump, etc., are all on this glacier, but its movements are not perceptible, if indeed it is moving at all.

OREGON.

MINING ITEMS.—Jacksonville *Sentinel*, Dec. 24: Ed. Hutt, one of the miners on Foot's creek, in making a partial clean-up last Monday, took out a nugget weighing $22. Along Foot's creek is some of the best mining ground in southern Oregon. There are five hydraulic mining companies at work on the left-hand fork of Foot's creek, and one on the right-hand fork of that stream. Three are worked with six-inch pipe, one with ten-inch, and one with eleven-inch pips. Work before last a slide occurred at the Squaw Lake company's ditch, which it took only a few days to shovel out. The ditch was never in better condition than now. Piping commenced Tuesday morning of last week on ground which had previously been thoroughly prospected. Notwithstanding there is 20 inches of snow on the ground, the company was piping at last account. The very light estimate usually placed on the gold yield of Jackson and Josephine counties by writers on Oregon, has induced us to make inquiry into this subject. There is no way to ascertain with certainty what the actual yield has been during the past 25 years, but from the most reliable sources of information we are satisfied that it has been quadruple the amount usually estimated. One individual alone, C. C. Beekman, of this place, informs us that he has, for himself and the express company, handled over $10,000,000 worth of gold dust since 1853, the largest portion of which was taken from Rich gulch, Jackson, Jackass and Sterling creeks. From his intimate knowledge of the business of other buyers, and from information derived from equally reliable sources in Josephine county, Mr. Beekman gives a decided opinion that at least as much more has passed through other hands from that date until the present. This would give an average yield of $500,000 per annum for the two counties, and when the really small amount of ground worked over is considered an approximation of the probable future yield of gold in southern Oregon would seem fabulous and incredible. Hydraulic mining is proving successful wherever sufficient water can be obtained, and it seems as if mining in this end of the State was just commencing.

UTAH.

ITEMS.—Silver Reef *Miner*, Dec. 20: The Kinner continues to furnish the Leeds mill with about 15 tons of ore a day. The recently-ordered hoisting machinery will probably not reach here for three weeks yet. The Thompson & McNally is shipping about 20 tons of ore to the mill daily. On this property the Bemis shaft is now down 24 ft, from the bottom of which drifts north and south are being run. The drift north is now in over 30 ft on a 2½-ft vein of good ore. An inclins west, following the dip of the vein, is also down about 20 ft. In the south stops, at the main works, some very rich ore has been found.

WASHINGTON.

IRON ORE.—Glympia *Transcript*, Dec. 20: Deposits of iron ore have been known to exist in this vicinity for years past. In the marshes east of the city bog, ore has been found, as also in the Black hills, a few miles west. About Black lake, when Government surveys were made, many years ago, the attraction was so great the compass was useless. We have no doubt but that it could be found in quantities sufficient to justify working, and would be a better bonanza to find than a silver mine.

SKAGIT GOLD.—Mr. E. G. English, of Mt. Vernon, was up from the Skagit on Wednesday, and had with him some of the Ruby Creek gold. It was fine, flake gold, good color, and is worth $17 per ounce. He informed us that the dust taken out at this mouth of Ruby creek, and on the Discovery claim on Canyon creek, is coaser, which leads miners to believe that there are several leads, and that probably quartz ledges will be found hereafter.

News in Brief.

INDIGNATION meetings continue to be held in Maine.

SALARIES of lower grade teachers in Stockton have been reduced 10%.

A MOVEMENT is on foot in New York to suppress female pedestrianism.

THE emigration fever has broken out again among the Southern negroes.

THE reported success of the electric light has caused another tumble in gas stocks.

WM. MCKEE, SR., proprietor of the *Globe-Democrat*, died at St Louis recently.

NEILL, the Illinois cattle king, whose liabilities aggregate $400,000, is still missing.

THE office of the Walla Walla (W. T.) *Statesman* was partially destroyed by fire recently.

THE Grangers' Bank of California has reduced its capital stock from $2,500,000 to $1,000,000.

MRS. CYNTHIA HODGDON, for malpractice, has been sentenced to State prison for ten years.

SPENCER, the missing Chicago Savings Bank President, is at present at Wurtemberg, Germany.

UPPER Pacific ports have been blockaded by ice during the cold snap, and steamers were frozen in.

DAN RICE, the circus clown, has become converted, and will at once enter the field as an evangelist.

OREGON is moving in the matter of inducing colored people to imigrate from the South to that State.

JAMES H. TURNER, editor of the *East Oregonian*, stabbed and killed a man at Pendleton, Or., on the 22d ult.

A SIX DAYS' pedestrian match is in progress at the Mechanics' pavilion in this city. There are 24 contestants.

THE export of cotton at New Orleans Saturday aggregated 46,300 bales—the largest on record in one day.

SAM WOODWARD and Seminole Joe, two murderers, were lynched, Sunday, at Golden, Colorado, by vigilants.

MAYOR KALLOCH, of San Francisco, has vetoed the ordinance granting a franchise to the Presidio Railroad Co.

CORRESPONDENCE has been discovered proving an alliance between the German Socialists and Russian Nihilists.

THE British troops in Afghanistan have recently experienced a change of fortune, and are victorious over the Afghans.

HON. R. E. LITTLE, a prominent Kentucky politician, was shot and killed at Louisville recently by his brother-in-law.

THE third annual session of the State Teachers' Association, convened in this city on the 29th ult., and continued three days.

HART, the colored man, was the winner in the late six days' pedestrian contest in New York, having made 540 miles.

IT is said that on the 1st of January J. C. Flood contemplates retiring from all active operations in the stock market.

THE severest weather reported for years has prevailed in Minnesota, the thermometer, Christmas, marking 40° below zero.

IT is rumored that Grant will succeed Scott as President of the Pennsylvania railroad, the latter's physical condition being hopeless.

LAWRENCE L. HOMER, the discoverer of the Homer Mining district, near Bodie, Mono county, recently suicided in San Francisco.

AT Oxford, Cumberland county, Nova Scotia, at daylight Sunday, the mercury fell to 35° below zero, lower than ever known before in that region.

MUCH anxiety is manifested among the Mormons over the rumor that Congress is about to take immediate steps toward the extinction of polygamy.

THE schooner *Mary D. Pomeroy*, from Crescent City for San Francisco, capsized off Point Reyes, and all on board, including 12 passengers, were probably lost.

†Deceased.

Decision on Riparian Rights.

The *Call* gives an outline of a decision which may he of local importance to all parts of the State. It seems that suit was commenced a long time ago by Leland Stanford, in the Nineteenth District Court, to enjoin J. J. Felt and William Stanton from diverting the waters of Franco's creek, San Mateo county, and for $4,000 damages. Subsequently the action was transferred to the Twelfth District Court, and tried. All of the parties in the suit own land on the hauk of the stream. The defendants are higher up the stream than Stanford, and it was shown hy the testimony that they had constructed a dam and conducted the water about three-quarters of a mile into a ten-acre reservoir. In this reservoir are natural springs, and it is also supplied from the hills. At no time is the stream very deep, and in summer there is scarcely enough water for domestic use and the support of animal life. Stanford keeps a number of horses on his farm, and he complained that the diverting of the waters of the stream rohhed his stock. The defendant said that he turned the waters from the creek to purify his reservoir hy running a stream through it, hut the evidence in the case proved that there was no outlet for it.

In passing upon the case, Judge Daingerfield said: The stream is too small to furnish water for irrigation, except for a small patch or garden spot, and without securing the same in small reservoirs, would not be sufficient for any such use. The general rule for such cases is, that the upper proprietor of land has the right to its use, and to divert it from the hed of the stream, if he return it without *material* diminution; hut this right of diversion would not apply in the case of a small stream that would he absolutely absorbed hy the diversion, or even greatly diminished. If the stream could be diverted and hy means of pipes or ditches conveyed to a reservoir, and from the reservoir again conducted to the stream, without further diminntion than would he caused hy domestic use, I douht not that a riparian owner could thus use it as against an owner lower down the stream, hut he could not use it for any but domestic purposes, such as the support of animal life in its fullest vigor. He could not use it in any way so as to deprive his neighhor of water for the snpport and comfort of animal life.

Puhlic policy dictates that an element so necessary and useful as water should be fully utilized, hut it must always he used with regard first to the support of animal life and domestic purposes, and the *surplus alone* can he diverted to any other use. From the views above expressed, and the finding of facts filed herein, it follows that the defendants must he enjoined from diverting, in any way, the waters of Franco's creek from the hed of the stream.

THE weather is milder in England and on the continent. At Paris it is thawing, after 30 days of frost, during which the thermometer touched 8° below zero. It was the coldest weather on record there.

AN appalling railway disaster occnrred last Sunday in Scotland. The hridge over the Frith of Tay was wrecked hy a gale while a passenger train was crossing, plunging the cars into the sea, and drowning over 90 persons.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention :

OVERALLS.—Isidor Lowonberg, S. F. No. 222,921. Patented Dec. 23, 1879. This inven. tion relates to certain improvements in the manufactnre of overalls, pants and other similar garments, bnt it is especially adapted to overalls which are of coarse, strong material and adapted for outside wear. It consists in the combination of a peculiarly shaped waist band, either with or without re-enforcing projections for tbe pocket openings, with a peculiarly curved back strap in two pieces, and cut independent of the waist band, tbe froe ends of said strap being nearly or quite horizontal, while tbe opposite ends curve upward and backward beneatb the waist band.

FRUIT DRIERS.—Geo. W. Dietzler, S. F. No. 222,874. Patented Dec. 23, 1879. This device relates to improvemonta in the construction of air-heating furnaces; in the application of said furnaces to the evaporation of the moisture from vegetable and othor substances, and the warming and ventilation of apartments, and also in a methed of supplying tbe combustion in tbe firo-box with air taken from tbe top of the evaporating chamber, or from near tho floor of apartments.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments :

Northern Belle, Dec. 20th, $9,953.38; Nortbern Belle, Dec. 22d, $6,833.14; Standard Con., Dec. 23d, $37,158.55; Belmont, Dec. 22d, $4,393; Belmont, Dec. 26th, $2,671; Bodie Con., Dec. 29th, $16,466; by Stage from Butte, Southern Montana, sbipped during Nov., $102.232; Richmond M. Co., Dec. 25th, $21,292.38; Dec. 28th, $8,554.23; Con. Virginia, Dec. 29th, $109,367; Union Con., $28,173.33.

A BERLIN correspondent of the *Morning Post* says he is authorized to contradict the rumors that a revival of an alliance between the three Emperors is contemplated. The correspondent also denies tbat any alterations are at present intended in protective tariff.

AN organization has hcen formed by the victims of Duncan (the ex-banker,) to prosecnte him, and if possihle, prevent him escaping State prison. Chief Jnstice Wallace has refnsed to rednce his bail below $113,000.

AT a meeting of the Skagit Trail Committee, bids were received for the construction of a pack trail from the head of navigation on tbe Skagit river to the new gold mines.

A NEW mining exchange has been formed in New York. The new Board is to be governed by similar rnles to the San Francisco and other stock exchanges.

THE North Bloomfield mining company have elected Thomas Bell, L. L. Robinson, Michael Castle, A. Locan and Thomas Brown as Trustees.

EVERY new snbscriber who does not receive the paper, and every old subscriber not credited on the label, within two weeks after paying for this paper, sbould write personally to the publishers without delay, to secure proper credit. This is necessary to protect ourselves and subscribers against the acts and mistakes of otbers.

A Good Article.

The last number of tbe MINING AND SCIENTIFIC PRESS has a good article on "Lucky Cuss Hill," from the pen of W. H. Seamens, our United States Deputy Revenue Collector. The article is accompanied by a diagram of the principal mines on the hill, which is a credit to the getter up. The article is well written and, like many other communications from Mr. Seamens, will draw favorable attention to Arizona mineral.—*Arizona Daily Star.*

A Cylinder Preeeman

Of good experience wants a situation in a S. F. or interior office. Understande running an engine. For a steady situatlou will accept moderate wages. Address "No. 2," this office.

An Engineer

Wante a eituation to run a stationary engine in ths city or country. Will accept a moderate salary. Address "No. 1," this office.

FRESH attractions are constantly added to **Woodward's Gardens**, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

BOUND VOLUMES OF THE PRESS.—We have a few sets of tbe back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce, and valuable for future reference and library use.

SAMPLE COPIES.—Occasionally we send copies of thie paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending ite circulation. We call the attentiou of such to our proepectus and terms of subscription, and requeet that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

F. S. MONROE, Secretary.

Patents for Mining and Farming Lands.

Having complete arrangements with competent and reliable parties in Washington City, by which wo are able to secure prompt and careful attention to law business there, we are prepared to assist Mill and Mine, Canal and Ditch owners in securing patents for their lands, mines and claims, in addition to our general line of patent business.

Many who are acquainted with the manner in which this business has heretofore been conducted, (witb or without assistance by local attorneys), will see at once the great advantage of patronizing an establisbment that is thoroughly organized and has its representatives in Washington to look after and prosecute their applications before the Commissioner of the General Land Office. The business on this Coast will be attended to personally by a member of our firm, and satisfaction will he given in all respects.

Correspondence from persons desirous of securing patents for Lands, Mines, Mill Sites, Canal and Ditcb property, promptly attended to.

Applicants for patents for mining and farming land, whose claims have been delayed for any reason, will find it to tbeir advantsge to consult with us and in case of necessity secure the services of our bome and Washington branch agency.

DEWEY & CO.,

Solicitors of Patents for Lands, Mines and Inventions, MINING AND SCIENTIFIC PRESS OFFICE, No 202 Sansome St., San Francisco.

The Large Circulation of the MINING AND SCIENTIFIC PRESS extends throughout the mining districts of California, Nevada, Utah, Colorado, Arizona, Idaho, Montana-British Columbia, and to other parts of Nortb and Soutb America. Established in 1860, it has long been the leading Mining Journal of tbe continent, its varied and reliable contents giving it a character popular with both its reading and advertising patrons.

Builders of Steam Machinery

IN ALL ITS BRANCHES,

Steamboat, Steamship, Land

Engines and Boilers,

HIGH PRESSURE OR COMPOUND.

STEAM VESSELS, of all kinds, built complete with Hulls of Wood, Iron or Composite.

ORDINARY ENGINES compounded when advisable.

STEAM LAUNCHES, Barges and Steam Tugs constructed with reference to the Trade in which they are to be employed. Speed, tonnage and draft of water guaranteed.

STEAM BOILERS. Particular attention given to the quality of the material and workmanship, and none but first-class work produced.

SUGAR MILLS AND SUGAR-MAKING MACHINERY made after the most approved plans. Also, all Boiler Iron Work connected therewith.

WATER PIPE, of Boiler or Sheet Iron, of any size made in suitable lengths for connecting together, sheets rolled, punched, and packed for shipment ready to be riveted on the ground.

HYDRAULIC RIVETING. Boiler Work and Water Pipe made by this establishment, rivcted by Hydraulic Riveting Machinery, that quality of work being far superior to hand work.

SHIP WORK. Ship and Steam Capstains, Steam Winches, Air and Circulating Pumps, made after the most approved plans.

PUMPS. Direct Acting Pumps, for Irrigation or City Water Works purposes, built with the celebrated Davy Valve Motion, superior to any other Pump.

San Francisco Pioneer Screen Works

J. W. QUICK, MANUFACTURER,

Several first premiums received for Quartz Mill Screens, and Perforated Sheet Metals of every description. I would call special attention to my SLOT CUT and SLOT PUNCHED SCREENS, which are attracting much attention and giving universal satisfaction. This is the only establishment on the coast devoted exclusively to the manufacture of Screens. Mill owners using Battery Screens extensively can contract for large supplies at favorable rates Orders solicited and promptly attended to.

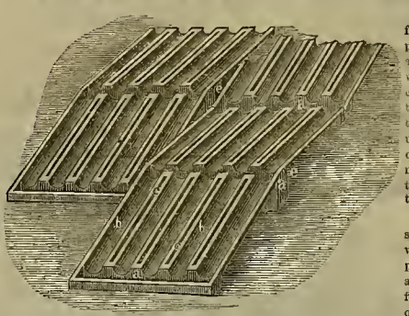
Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

Howland's Under-current, Mill and Sluice Riffle.



This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

SAN FRANCISCO, SATURDAY, JANUARY 10, 1880.

VOLUME XL Number 2.

The Clayton Air Compressor.

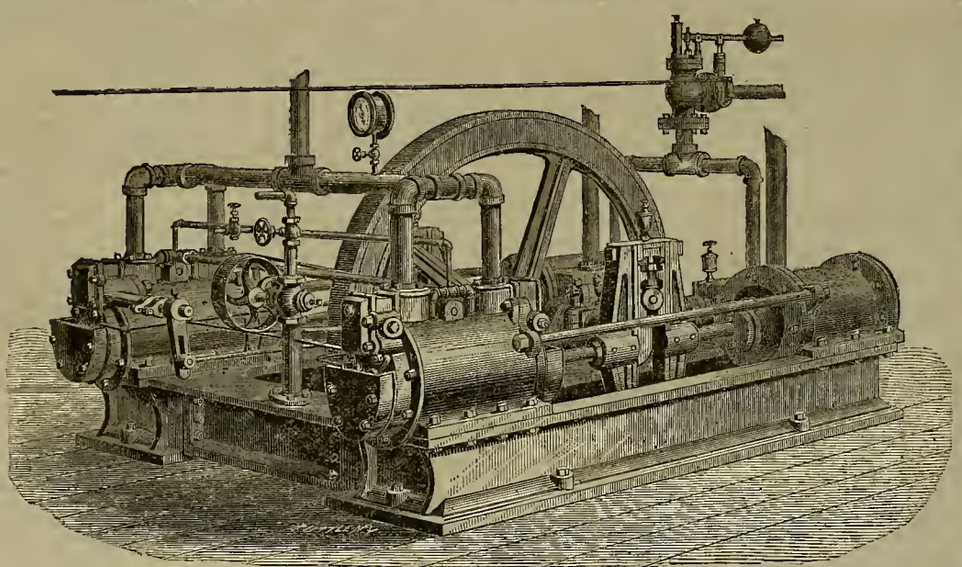
We have the pleasurs of prssenting this week to the rcaders of the PRESS an illustration and dscription of an improvsd air compressor, built by sn Eastern manufactursr, whose skill, in adapting his specialties in machinery to ths requirsments of different locations and special pnrposes for which employed, has long bssn recognized and appreciated in the more immediate neighborhood of tho manufactory, and also on our own Pacific coast.

While adding much to the value of the air-compressing mecbauism, a general design of machine has been closely adhered to, which has been favorably known to ths public for sovsral years.

In the transmission of power from the steam cylinder to the fly-wheel, which in this case is used only to equaliza ths motion and strains consequent upon the different positions occupisd by ths crank during the stroke, tho ordinary connecting rod is dispensed with (as seen in ths cut) and a "slotted cross-head" substituted for it, which furnishes a rigid and direct connection between the steam and air pistons and very materially reduces hoth the weight and space required for a given size. The crank-pin hoxes slide up and down in this "cross-head" or yoke, and are provided with an ingenious and efficisnt means of "taking np," at one operation ths wear of both the crank-pin and slides, and furthermore, allows the wear to be tsken up *uniformly* on both sides of ths crank-pin, thus maintaining "uniform clearance" hetween the pistons and each cover of hoth steam and air-cylinders. Ths foot of ths slotted cross-head or yoks is provided with "adjustabls brasses" which rest on a "slipper guide" (not shown in cut) which supports all the weight attached to ths piston rods, between the two cylinder covers, and contributes much to "uniform and true wear" of both cylinder and pistons. These improvements in construction are designed to meet the ohjections hitherto urged against such a method of transmitting power from the piston to the fly-wheel; hut whenever the ordinary cross-head guide bars and connecting rod are preferred, they ars furnished at a small advance in cost. The steam piston is provided with spring rings and approved msans for setting thsm out. The induction and eduction of the steam to the cylinder is controlled by a plain slide valve, properly proportioned, which in turn is actuated by an eccentric on ths main shaft.

In compressing air, a great amount of heat is developed, which, if not conveyed away at each stroke, would scriously retard, and finally stop the working of the compressor. To successfully do this with the smallest expenditure of water (an important item in somo locations), has been one of the problems claiming the attention of those engaged in huilding air compressors. Of tbe three methods of cooling which have successively heen employed, that of circulating cold water through a "water jacket" surrounding the air cylinder, has been generally adopted in Americau practice. While heing governed hy the experiments and experience of the past in the selection of a method of cooliug the air cylinder, the manufacturer of this compressor has certainly made a step in advance, aud in the right direction in its application, and it is claimed accomplishes important results. The degree of heat developed heing proportionate to the pressure, it necessarily follows that the ends of the cylinders are exposed at each stroke to air heated to a much higher temperature than the middle of the cylinder, and under such conditions there would he a tendency to unequal expansion of thc cylinder greatest at the ende and least in the center, whicb we are informed has in prsctice seemingly givsn a permansnt "set" to the mstal. To correct this tsndency, ths cold water is introduced to the "jacket" at each end of the cylinder, travsrsing the cylindsr circumferentially and having its outlet at the csntsr. This brings the watsr first in contact with the "bottest" parts of the cylinder, and as it hecomss gradnally heated by transmission to it of heat from ths metal in contact with it, its flow is dirscted by bridge walls over successive sections of metal lcss hsatcd, and following a wsll-known law, the warmsr water absorhs lsss heat from the cooler metal. It is claimed by this system of "jacketing" that uniform expansion and "sizs of bore" is scoured with no tendsncy to "bind" ths piston in the middle of the stroke and allow leakage at the ends.

Another feature wbich we belisvs is introducsd in connection with air compression for the first tims is that of opening, by a direct and positive connection with the main shaft, of the "delivsry valves" whenever the air in the cylindsr reaches ths same pressure as that in ths "receiver," or pipes that convsy it away. Systsms of "halanced valves" for this purposs which has yet been dsvised have not given very satisfactory results in practice, while for durability and gensrally satisfactory working, none has given so good rsults, under tbe vary-



THE CLAYTON NEW AND IMPROVED DUPLEX AIR COMPRESSOR.

ing circumstances under which compressors are called to work, as a "heat valve." The first rsquisite of any valve is that it shall be, and remain, tight, ths attsinment of which necessitates such a disproportion between the relative area of valve against which the air in tho cylinder acts to lift the discharge valve from its scat, and that upon which the air in the "receiver" or pipes passee tending to confine it to its seat, that in practice the air in the cylinder is compressed up to a pressure from 30% to 50% greater than that constantly maintained in the receiver before it can make its escape. Any compression of the air in the cylinder above the "working pressure" is an absolute waste of power, and eubjects the compressor to eevere and unnecessary strains. In order to retain the "heat valve" with its valuahle features, and at the same time relieve the compressor of unnecessary shocks and strains, a device, in part shown in the illustration, is applied to the air cylinder, positive in movement, which lifts the discharge valve from its seat when the air in the compressor cylinder has reached the pressure maintained in the "receiver" and pipes. Between all the air valves and their respective seatings there is interposed a duplicate valve turned perfectly true, and it will maintain its form nnder the action of the valves, and yet possesses elasticity sufficient to protect the valve and seat.

While it is necessary to use efficient means to keep the oylinder cool, as before explained, it is of the highest importance that both cylinder and piston should bs properly lubricated, and means providsd for expslling all ths compressed air from ths cylinder at the complstion of each half stroke. Any air rsmaining in ths cylinder after ths piston commsnces its rsturn movsment, will re-expand to its original volume and pressuro before any further supply of air will flow in. From this it will be apparent that a very small amount of compressed air unexpelled in ths cylinder will vsry materially *reduce the capacity* of the compressor. To effect the desired lubrication of the cylinder and to fill all waste and clearancs spaces hetwsen ths face of the piston and dischargs valvss, a lubricating cock is arranged between the two air cylindsrs (seen at the left hand of the cut), whioh ie operated by bslt from the shaft.

At the commsncement of each return movemsnt of ths piston this lubricator delivers to the cylinder, through the inlet valves, a measured quantity of oil or water, which remains at the bottom of the cylinder during ths period of air admission, but when the inlet valves close and compression commences it slowly risss, and at the end of the stroke hss filled all the "clearance" and space below the point at which the air is delivsrsd. By a simple arrangemsnt of pipss connscting tbis lubricator with the air receiver (not shown) the same lubricating matsrial may be, if desired, used ovsr and ovsr again indefinitely.

At the right hand of the engraving, placed upon ths steam supply pipes, is Steels' patsnt air governor, which is used exclusively on the compressore and pumps made at the Clayton Stcam Pump Works. This governor is operated hy the compressed air, and may be set to act at any desired pressure by eimply changing the position of the weight on the lever of the governor and will stop the compressor whenever the air pressure exceeds the desired point, readmitting steam when the air pressure falls.

From the foregoing it is apparent that the manufacturer has closely studied the wants of the "trade," and introduced such improvemente which, combined with thoroughly good materials and workmanship, make an air compressor, which, in the hands of practical men, will be descrvingly successful and popular.

These compressors, together with air and steam pumps, are built in a great variety of sizes and forms, single or duplex, to be driven by eteam, water or by beit, and are fully illustrated and described in a circular issued by the manufacturer and patsntee, James Clayton, 14 and 16 Water etreet, Brooklyn, N. Y.

On the island of Mauritiue 20,000 cattle have died of the plague.

Annual Meeting of the Academy of Sciences.

The annual meeting of the California Academy of Sciences was held on Monday ths 5th inst.

Vice-Presidsnt Moore read a report of tbe Academy's progress dnring the past year, and William Ashburner, Chairman of the Board of Trustees, also read a report. Ths annual reports of Chas. Troysr, Librarian; W. G. W. Harford, Director of the Mussum, and Elisha Brooks, Treasurer, were also read. The report of ths Secretary, Charlcs G. Yale, ehowed rescipts amounting to $11,129.92 during the year, comprising $4,000 borrowsd from the Bank of California to pay taxes, $3,445 from the Market street property, $1,707.50 dues, and $400 from rent of the hall. Ths dishurssments aggregated $11,152.87, embracing $2,120 paid the bank, and $5,522 taxes and sundry othsr matters. The taxes referred to are on ths Market-street property, given to the Academy by the late Jamss Lick. Ths taxes have hitherto exceeded the income from rents, so the property has been a dead weight to the Academy.

A vots of thanks was passsd to Mr. Yale, Secrstary, for gratuitously performing the duties of his offics both for the Academy and to the Trustees; and to Mr. S. B. Christy as corresponding Secretary. A vots of thanks was also passed to both of these gentlemen, in conjunction with Messrs. Dewey & Co., publishers of ths SCIENTIFIO PRESS SUPPLEMENT, for the preparation and publication of papers read before the Academy. It was shown that had not Messrs. Dewey & Co. given space in ths SUPPLEMENT to the papsrs read before the Academy, the work of the members could not have been published.

Messrs. W. A. Wallace and J. B. Swecnsy were elected resident members; and Messrs. A. T. Dewey and W. B. Ewer were proposed for membership. The Secretary read for Prof. Davidson, in his absence, a paper on the Solar Eclipse, which we give in another column. Ths officers elected at the ballot held during the day to serve during the year 1880 were announced as follows, all incumbents heing re-elected: President, George Davidson; First Vice-President, J. P. Moore; Second Vice-President, Hermsnn Bshr; Recording Secretary, Charles G. Yale; Corresponding Secretary, S. B. Christy; Treasurer, Elisha Brooks; Librarian, Charles Troyer; Director of Museum, W. G. W. Harford; Trustees—William Ashburner, R. E. C. Stearns, George E. Gray, B. B. Redding, Thomas P. Madden, Ralpb C. Harrison and J. M. McDonald.

A GOVERNMENT MINING COMMISSION.—A joint resolution has becn introduced in Congrese by Page, providing for the appointment of a commission to investigate the debris question in California, to he known as the Commission on Mines and Mining, to he composed of five members, three to be designated by the Secretary of War from officers of the Corps of Eugineers of the United States Army, one of whom at least shall have eerved and resided within the State of California, and two to be designated hy the Secretary of the Treasury from officers of the Coast Survey. Said commission shall institute such scientific and practical examination into the eystem and operations of hydraulic and other kinds of mining, in their relations to the navigahle waters of California and agricultural lands adjacent to the streams receiving the deposits of said mines, as may he considered necessary for the discovery of some practicahle and feasihle method for the protection of the rivers aforesaid and the lands otherwise affected by the mining operations of the State.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds

Something About Jute.

Editors Press:—I am frequently asked for information on the culture of the jute plant and the preparation of the fiber; where seed is to be had, etc. With your permission I will take this method of giving what information I have on the subject through medium of the Press. I have never seen jute in cultivation; all that I know about it has been gained by correspondence and the reports of the Agricultural Department at Washington, from which I infer that the plant can be grown in California to as great perfection as it ever grew in India.

In the year 1870 the Agricultural Department at Washington, distributed jute seed in small quantities through the Southern States. The next year the Department was furnished with favorable accounts of the growth of the plant, but the planters were still at a loss as to the best mode of planting the seed, harvesting the crop, separating the fiber from the stem, etc. Hon. E. H. Derbey of Boston, addressed a letter to Mr. R. McAlister, then residing in Calcutta, and received the following:

The seed is sown in the month of March and April, broadcast on prepared ground, preference being given to moist, high ground situated if convenient on the bank of a river and somewhat sandy. It is not necessary to irrigate the ground, as no more water is required than is sufficient to keep the roots moist. It is allowed to grow three to four months and is cut in the months of June and July and August, when it has attained the hight of eight to twelve feet; the size depending on the soil and season. The time for cutting is just after the flowers have turned to seed and before the seed begins to ripen. When cut, the stalks are tied in small bundles and thrown into tanks of dirty water and allowed to remain there five to eight days to rot, at the expiration of which time they are taken out and the fiber falls from the stalk. It is then hung up to dry, and when dry it is sorted, packed in round bundles called drums, and sent to market. If all the plants were allowed to ripen the yield of seed would be about 120 lbs. per acre. The quantity of seed required to be planted is from 30 to 40 lbs. per acre.

I am not prepared to give information where jute seed can be had at this time, but would suggest that Mr. Sussman, the Secretary of the Pacific Jute Company, San Francisco, would be likely to know and assist in procuring seed.

From other reports I learn that the yield of fiber is from 2,000 to 3,000 pounds per acre, and that the labor and cost is one-fourth that of cotton.

There are several other methods of separating the fiber from the stalk, than the one given by Mr. McAlister, but as yet there is no machine invented to separate the fiber from the stem, for the reason that there has not been any demand for it yet. Jute must be raised in some considerable quantities, and the necessity for a machine be apparent before the attention of inventors and machinists will be generally attracted to it.

The planters have been very cautious about venturing into the cultivation of jute on account of having to compete with the cheap labor of India; but if we are not misinformed it can be made profitable in California where there is a local demand for 20,000 tons per annum, with a fair prospect that within a few years the demand will reach 50,000 or 60,000 tons. Admitting that we use the primitive method of the natives of India, and obtain the fibers by hand labor, we save the freight from India, and duty, commission, insurance, etc. The same people picked the seed from cotton for hundreds of years by hand until American ingenuity made the cotton-gin. It is just as reasonable to suppose that we will invent a machine that will more than compete with the cheap labor of India just so soon as there is a demand for it.

For further information as to the probable profits of jute culture, I refer those who entertain the idea of growing jute to the reports of the Commissioner of Agriculture from 1871 to 1878; there is much information in all the reports.

Prof. Waterhouse of the Washington University, St. Louis, has written a very interesting article on the importance of the culture of jute. After visiting the jute-growing country in India he is well prepared to give information. He says the trials that have been made strengthen hope into an assurance that jute can be successfully cultivated in the Gulf States and in southern California. Again he says, what has been so successfully accomplished in Dundee can be done with a still greater success in the United States. We cannot only spin and weave the fiber, but we can also raise it; we not only can derive the profits of making the fabrics, but we can also enrich ourselves by the twofold economies of the growth and manufacture of the staple. Again he says: During the last five years about 170,000,000 pounds of jute were made into paper in the United States. The newspapers of the United States ought actively to promote an undertaking the success of which would so greatly rebound to their own advantage.

In conclusion I would recommend to those having suitable land and a disposition to try it, that they get seed in quantity enough to make it an object, go at it with the intention of making money and doing a good thing for the State. There is good land to grow jute in Fresno and Kern counties, as well as many thousands of acres elsewhere in the State that will produce it profitably. Wm. H. Rector.

Notes from Richmond Basin, Arizona.

Editors Press:—Thinking perhaps a few items from this locality might interest your readers, will say that in all my traveling and examinations in this portion of the Territory have found in this Basin and the surrounding country a larger and richer amount of ore than I had supposed had been taken from any mines in this belt; and foremost in the ranks is the celebrated Silver Nugget, which has without doubt more ore mined, and on the dumps ready for milling, than any other in the Territory, and for quality, as well as quantity, I think it as good as any, for, as near as I can estimate, there is now somewhere about six thousand tons which will average at the least $75 per ton. This is called second-class ore, the first-class having been sorted out and the most of it shipped, which ranges into the thousands. Having examined the surface, I found that there had been sunk on the property eight shafts, from fifty to one hundred feet deep, and all show a fine body of mineral. Here I found drifts and crosscuts have been run on the vein, and all show good ore. At the depth of fifty feet the crosscut west is twenty feet long, and still in ledge matter. A crosscut east of twelve feet is still in ore, so that the width is hard to determine, making the Silver Nugget one of the most valuable properties I have found since I have arrived here.

At the northeast of the Nugget is the McMorris, which has been purchased by some Eastern men. Here we find ore as rich as anyone could ask for, and in goodly quantities. This has never had but little work done, for the reason that at a small depth water was encountered, and the former owners' means wouldn't allow the purchase of machinery for raising it. The present owners are starting work with the intention of developing it thoroughly and making a mine of it, and they have all the assurance of having their labor rewarded by a large return of bullion. Adjoining this on the west is the Richmond, and here I find a splendid prospect for the work done. At the present time in the east drift there is a showing of extremely rich ore. This shows a vein of pay ore nine feet wide in this drift and no walls in sight. About one and one half miles southeast of here is the famous Buckeye, which has in sight a large amount of high-grade ore. This has been opened by shafts, tunnels and drifts. One shaft is 235 feet deep and shows a width of ledge of ten feet and three feet of high-grade ore, some having native silver. This is owned by San Francisco capital, and they have a bonanza.

About two miles west of this there has been found a good prospect in the way of a rich carbonate vein. This is the first ore of this character found in this vicinity, and the owners are hoping for a second Leadville to start up. This is a large, strong vein, and has a splendid formation holding it, and in the gulch, at a distance of three hundred feet, is the most favorable location for reduction works, as there is water here the year around. This location has been selected for the Nugget mill, which has just been shipped from San Francisco, and when that, together with the McMorris, gets to working, am satisfied that this portion of the Territory will have lots of friends. With more anon, will close. Miner.

Richmond Basin, Dec. 23, 1879.

What is the Patent?

Editors Press:—It is perhaps not surprising that patents should be somewhat loosely granted occasionally, for, besides that it is impossible for the examiners to know all that has been done, it may well be supposed they sometimes think that, inasmuch as a patent is not a fixed fact till it has passed the ordeal of the courts, it is as well, when one is demanded by a person who ought to know more of the subject than they do, to take his money, grant the patent, and let him take the chances of maintaining it against anyone who may choose to contest its validity.

No doubt some clearly invalid patents are taken out on the calculation that many people will rather pay a small royalty than incur the expense of a lawsuit; but, really, it is fast coming to this, that it will be dangerous to adopt the most obvious suggestion of common sense, lest it should prove to be an infringement of some patent *wrong*.

The immediate occasion of these remarks is the description of "Hofmann's patented process," in your issue of December 27th. It is difficult to see, in that description, anything which deserves the protection of a patent. Who is to prevent me from treating ore by the Patera process first, and by the Plattner process afterward?

At the works referred to in the description, the ore is first treated by the well-known Patera process, including the roasting with steam, for the extraction of silver, and afterwards by the equally well-known Plattner process for the gold. The mechanical details present nothing new, except possibly the conducting the waste chlorine to the furnace, which is of no importance.

The process, as a whole, is not more novel than was the so-called "Kustel & Hofmann" process for gold and silver, differing from it only in the reversal of the order in which the processes of Plattner and Patera are applied to the ore. It is not more novel than the retreatment of tailings produced by one well-known process, by another well-known process, for the more complete extraction of the contained metals. Is that how Mr. Hofmann's patent reads?

C. H. A.

The Age of Gold.

From a lecture before the "Bullion Club," of New York, delivered by Prof. Benjamin Silliman, the New York *Exchange* makes the following synopsis: He began by referring to the fact that nature holds the original sources of wealth, and that labor only creates values, all effort to create them or exchange them permanently by human law-making being a direct violation of a great natural law. "What is money?" said Prof. Silliman. "There is a substantial agreement that money is a common medium of exchange among civilized nations. The choice of the world from the earliest time has been either silver or gold as money, because these metals demand value: (1) from the labor which it costs to obtain them; (2) they are little liable to injury or destruction by use or accident; (3) they are readily divided into coins of convenient size; (4) their transportation costs only a small portion of their value, and (5) their quantity, although limited, may always be increased by mining to replace the loss arising from consumption and to meet the wants of the growing population of the world. No other known substances possess this collective group of attributes fitting them to be used as money. Platinum was tried by the Russian government some time since without success. The preference for gold as a medium of exchange was because gold possessed the power to resist the ravages of time and the action of chemical substances which destroy silver. The value of bank notes, checks, bills of lading, notes of hand and other substitutes for coin is precisely in proportion to the credit of their maker. Coin sinks into the character of bullion when its purity or standard is tampered with. Prof. Silliman referred in severe terms to the experiment of the government of coining a debased silver dollar, and said: "Legislation is impotent to create values or make 2 and 2 equal 5. History proves that all experiments to discover and put in use any description of circulating medium, except such as has been and is immediately convertible into gold or silver, are disastrous failures."

At the time of the discovery of America the total value of the gold and silver known to exist in the world was estimated at $170,000,000.

The total gold product of America in the 53 years from 1492 to 1545 was $148,400,000.

In 1500 the silver mines of Potosi, Mexico, were discovered, which were destined to produce more than $1,000,000,000 in silver between 1556 and 1803. The stock of gold and silver in commerce about the year 1600 was:

Gold (37%)	£200,000,000
Silver (63%)	340,000,000
Total	£540,000,000

Between 1600 and 1800 the stock of metals was swollen by:

Gold (30%)	£420,000,000
Silver (70%)	996,000,000
Total	£1,416,000,000
Add stock in 1600	540,000,000
Total	£1,956,000,000
Add product from 1800 to 1848:	
Gold	£158,000,000
Silver	450,000,000

On the authority of Humboldt and Chevalier, continued the Professor, the silver production of Mexico and South America was as follows:

From 1545 to 1845 about—	
Bolivia and Peru	$2,580,000,000
Mexico	2,701,000,000
Chile	6,967,249
Total	$5,292,967,249
From 1845 to 1880—	
Mexico	$700,000,000
Bolivia and Peru	245,000,000
Total	$6,237,967,249

The "age of gold" was inaugurated by the discovery of gold in California in 1847. In the 300 years following the discovery of America the influx of silver and gold into commerce from America alone increased the volume of the precious metals previously existing nearly forty-fold in nominal value. The coin in existence at the close of 1809 was £380,000,000. Let us now see how the enormous discrepancy between this sum and the output of silver from America alone previous to 1847 can be accounted for:

American silver and gold production, say	$6,000,000,000
Coin in existence in 1809	$1,843,000,000
Absorbed by Asia	1,700,000,000
Consumed in the arts	1,700,000,000
Wear and tear	106,000,000
Lost or hoarded	651,000,000
	$6,000,000,000

The Asiatic absorption of silver, Prof. Silliman said, was the most remarkable of financial problems. This phenomenon, acting with the great increase of gold during the 20 years following the discovery of California's gold, disturbed the long-established ratio between the two metals, and for a time advanced the silver to a premium in France and other European countries. Dividing the history of the precious metals into four periods, the fluctuation of ratios was as follows: First period, B. C. 1600 to A. D. 312—The ancient relation between silver and gold in the Orient was 1 to 13.33, falling as low as 1 to 8 and 8.93 about B. C. 100, consequent on the increase of gold brought by Cæsar out of Gaul. Second period, A. D. 864 to 1500—The market ratio was 1 to 12. Third period, from 1492 to the opening of the gold mines of California and Australia. Early in the 17th century the ratio rose to 1–15.40; after 1687, down to 1771, it was 1–14.80. In 1550 the production of silver was several times greater than that of gold, and the ratio was 1–11 to about 1–15, but before the close of the 17th century it had reached 1–15.5—the ratio which is still the French standard. Fourth period, 1851 to date—The prediction of many who anticipated a marked fall in the price of gold, consequent upon the enormous increase in the output from 1847 to 1853 were not sustained by the result. In 1851 the ratio was 15–46; in 1852, 15–57; in 1853-54, 15–33; and in 1855, 15–36. After 1864 it began to rise, being in that year 15–40; from 1868 to 1870, 15–60; in 1873, 15–90; and in October, 1874, 16–38. The Professor submitted the following table showing the relative production of gold and silver in the last period:

Years.	Gold.	Silver.
1833–42	£15,000,000	£30,000,000
1843–52	86,000,000	50,000,000
1853–62	257,000,000	82,000,000
1863–72	230,000,000	106,000,000
1873	21,000,000	14,000,000
1874	18,000,000	16,000,000
1875	20,000,000	16,000,000

In 1600 the value of silver to gold was about as 12 to 1; in 1800, about 15½ to 1, while the stock of silver had been increased only about 5%. Prof. Silliman thought that America was destined to be the largest producer of gold and silver in the world. In conclusion, he said that both gold and silver from the earliest times have been adopted by mankind as the most convenient materials for money; that gold properly is recognized as the chief medium of value, but that the principal cause of the depreciation of silver was its demonetization by Germany; and that upon the precious metals alone is it profitable to maintain a bank-note circulation, and it made no matter whether the entire mass of the reserve gold and silver was in coin or in fine bars. "We believe that with a wise course of national legislation, the removal from the United States notes of their legal-tender quality, and the retention of ample reserves of gold and silver, will permanently maintain and renew the financial credit of the nation, and give us, in the best sense of the term, the age of gold."

Formation of Coal.

The Director of the Museum of the Parisian Academie des Scienees, M. Fremy, recently read a paper under the title "Chemical Researches respecting the Formation of Coal," which is of great interest. It is known that coal is produced by the decomposition of vegetable matter, which for many ages covered the surface of the earth. The learned chemist has made a series of analyses, of which he gives an account in his paper, and which have enabled him to establish the laws of this decomposition, and to explain the transformation of the tissues of the vegetable matter into coal by the loss of their organic form.

With reference to peat, the hypothesis has been put forth generally up to the present time of a possible relation between their formation and that of coal. M. Fremy has been led by the same investigations to the conclusion that the peaty formation is, so to speak, the first stage reached by the ligneous tissues before arriving at their complete transformation into coal.

The paper gives the result of investigations on the vegetable tissues which Mr. Fremy has carried on since 1850. Our space will not permit us to give anything but the conclusions drawn from the experiments, which are as follows:

1. Coal is a substance which proceeds from the transformation of vegetable matter, but which no longer preserves its organic form.

2. The vegetable marks which the coal presents are produced by it, as in schist or other mineral substances, and do not prove its organization. This fuel is a bituminous and plastic matter, on which the external features of the vegetation are molded. When a piece of coal presents on its surface, or within its interior, marks of vegetation, it is not to be thence inferred that the adjacent parts are necessarily the result of the alteration of the tissues which were covered by the membranee whose form has been preserved.

3. The principal bodies contained in the vegetable cells, submitted to the double influence of heat and pressure, produce substances which present the properties and composition of coal.

4. The coloring, resinous and fatty matters contained in the leaves are changed, by the action of heat and pressure, into substances which approach very nearly to natural bitumen.

5. With regard to the ligneous tissues at the base of the *cellulose* and the *vasculose*, they are not transformed directly into coal. Before being so changed they pass through a process of peaty fermentation, which produces ulmic acid. It is only in the second place that this ulmic acid is transformed into coal, mingling with all the coal-forming substances produced by the contents of the cells.

Mechanical Progress.

Strength of Wrought-Iron Railway Axles.

At a meeting of the English Society of Engineers, held October 5th, a paper was read on this subject by Mr. Thomas Andrews. The author gave at the outset a brief historic sketch of the Wortley Iron Works, Sheffield, at which works some of the first railway axles used at the commencement of the railway system were made, and, as an interesting fact, he mentioned that these works were supposed to have been established at the time of the Roman conquest. He enumerated a series of practical experiments which he had conducted with a view of showing the great resistance which best fagoted scrap axles are capable of offering to sudden strains, and considered at some length the question of iron *versus* steel as a material for axles. The chief standard tests employed by railway companies and engineers were then given, and their relative merits pointed out. Then followed an account of a large number of experiments on axles manufactured by the author to comply with the various tests. These results tended to show that in some cases the deflection of the axles became less as the number of blows to which they were subjected increased, which it was thought might be due to the heavy blows having a tendency to alter the molecular structure of the iron, and render it more crystalline. From various other experiments which were given, it was shown that the actual quality and tensile strength of an axle might be misjudged, and wrong conclusions formed as to its quality, by solely relying on a falling test. The author strongly advocated one uniform test for axles, and thought that in any correct process of axle testing the amount of testing force actually applied should be measurable, and bear some relative proportion to the greatest amount of shocks to which an axle was likely to be subjected in actual working, and suggested that it would be desirable to obtain, by accurate experiments, an approximate estimate of the work done by the axle in ordinary working, and to arrange some test which could be universally agreed upon.

Welding Steel Hammers.—A correspondent in the *English Mechanic* asks if it is possible to weld a face on a cast-steel hammer. The answer given is as follows: "I suppose to make it heavier; this cannot be done even with sheer steel. Many men will assert that they have seen it done many times. Files may be put together very easy and to look sound, but as to their being welded I doubt it very much. Sometimes old swords can be put together to look sound, still they are not so. Many workmen are not aware that there is a kind of steel made, called welded steel; this will account for so much cast steel being welded. I know one firm that sent an order for 100 tons of sheer steel to one of our best steel makers, and they, not having it in stock, sent welding cast steel, and it gave great satisfaction, and as the order came from a Sheffield firm no doubt it was tested very severely as to its welding property. Of course, the firm it was for took it for sheer steel, and no doubt had the order been for cast steel the same would have been sent, that is if no other was in stock. I have some cast steel and I know it is the right sort, and I should like to give anybody a piece who would try to weld it. I have seen this kind of thing tried in many of our best workshops and by some of our best workmen hundreds of times, and welding files I regard as an old tale."

Composite (or steel-faced) armor plates are rolled at one of the leading Sheffield works, in the following manner: To the iron armor plate to be faced, is attached a frame of iron bars. This frame is capable of holding a quantity of steel, about half the thickness of the iron plate, and, when fixed, is placed in the furnace and brought to a welding heat. On withdrawal the frame is filled with Bessemer steel, and after cooling, is reheated and rolled in the usual manner. The finished plate is iron on the back, while the face is of steel. The *English Mechanic*, describing these plates, declares that their power of resistance is something wonderful. A shot, for example, that pierces a 12-inch iron plate, only makes an indent of from three to four inches in one of the "Composites," and a nine-inch steel-faced plate is affirmed to be equal to a 12-inch iron plate. This fact, it is noticed, will permit of a considerable saving in the weight of armor; and armor-plated ships, thus provided, will be able to exhibit more rapidity in their movements, and will be more economical in their working. H. M. S. *Ajax* is to be supplied with plates made on this principle, some of which will be 16 inches in thickness.

Key-Hole Saw.—The Japanese hand saws cut on the pull-stroke; so no matter how hard the wood or dull the saw, they will not bend or buckle. It is rather more difficult to saw to line with such saws than with ours, but they have their advantages. Take one of our key-hole or compass saws, cutting on the push or shove stroke, what an aggravating, limber thing it is. Now point the teeth the other way, and you have a tool that will keep stiff no matter how many knots it encounters or how dull it gets. In other words, the pull-stroke of 3,000 years ago is the best for such thin, narrow blades.

Care in Emptying Steam Boilers.

In regard to emptying and blowing-off steam boilers, a French contemporary gives the following useful hints: "Those who possess externally-fired boilers, working only by day, have all observed that the fire being covered by night, and the doors closed, the pressure rises during the night, often sufficient to open the valves. This shows that the masonry, being at a much higher temperature than the boiler which it envelops, imparts to it some of its heat. The same effect of heating the boilers is produced, to a less degree it is true, but nevertheless to some extent on the outer jacket of internally-fired boilers. It is, consequently, injurious to empty boilers soon after having stopped them, because after emptying, the plates would be heated by the action of the masonry. It is well to admit a current of air through the flues some hours after the stoppage of the generator, and not to empty it before the flues become cooled to a temperature below 300°. When the flues are not too hot, no serious inconvenience is experienced in emptying the boiler under pressure. We do not say at high pressure, as for a boiler the pressure of which would be 10 pounds, the temperature of the water being 304°, a greater quantity of steam would be generated during the process of emptying; we think at a pressure of two pounds the boiler could very well be emptied. In internally-fired boilers, as there is no masonry to cool in the furnace tubes, it would be well to admit the current of air intended to cool the masonry behind the boiler, as in this case the furnaces would be cooled more rapidly than the jacket. We have sometimes seen owners empty their boilers almost immediately after the fires have been extinguished, clean them with cold water as soon as they were empty, and keep up a current of water so that the workmen might work there. Boilers of small dimensions sometimes resist such treatment, but in large boilers it will be seen that unequal contractions must take place, causing the rivets to burst."

A New Method of Making Steam Boilers. An English engineer named Whitehead, recently exhibited at Owlestan, near Sheffield, a boiler made on a new plan. In making this boiler a ring of steel is cast and heated; then it is placed upon a large roller, and by the aid of smaller rollers it is enlarged to the requisite dimensions. The ring is run from one end of the roller to the other, and is returned by reversing the machinery. The heads necessary for the completion of the boiler are subsequently put on with bolts. The machinery is rather expensive, and it is its cost which is said to be the point upon which the success of the invention hinges. The inventor claims that within six hours he can construct the shell of a boiler of a more durable nature than those now made with iron or steel plates riveted together. There is no doubt that such a boiler must be stronger, as the danger of tearing the seams on the cylindrical surface, where the strain is the strongest, is done away with by the total absence of such seams.

Cast-Iron Magnets.—M. Carre, says the *Revue Industrielle*, has published details of a process he has recently patented for manufacturing magnets in cast-iron. He melts soft metal, very slightly carbureted in the crucibles, and runs it into molds, adding from 10% to 15% of steel filings, according to the degree of carburation, to improve its quality. Good results are obtained by adding to the iron, when melted in the crucible, from 1% to 1.5% of nickel, and 25 to 30 thousandths of copper, or 2% of tin and 50 thousandths of copper. The addition of the copper and tin to the iron facilitates tempering it at comparatively low heat. The quantities of the added metals can be reduced without detriment by tempering at a higher temperature as their proportion is decreased. The best result is obtained by tempering pure cast-iron at as high a temperature as possible short of a degree of heat which would misshape the molded pieces, or expose them to fracture.

The Band Saw Action.—The teeth of a circular saw act at varying angles on the grain of the wood; those at the top of a log being ripped, striking the fibers at a more acute angle, and consequently to better advantage than those at the bottom. The band saw teeth, on the contrary, all meet the fibers at the same angle; and this, as the table is ordinarily arranged, is as squarely across them as is possible. To remedy this, Mr. Pryibil, of New York, inclined the table of one of his band sawing machines about 23½°, so that the board to be ripped was fed uphill, and the teeth met it at a considerable acute angle. He reports that the traction, or effort of feeding, was lessened by one-third, as measured by a spring balance. The cutting action under these circumstances was undoubtedly much more favorable than when the teeth struck square across, but no dynamometrical test was made.

New Kind of Plated Sheet Iron.—In Iserlohn, Westphalia, thin sheet-iron is plated with alloys of nickel or cobalt and manganese. A half of one per cent. of manganese makes cobalt and nickel a very malleable fluid when melted, and ductile. The plates, which are already in the market, are beautifully white and brilliant.

Steel vs. Iron.—Some authorities predict that in a few years steel will supersede iron in naval architecture, to as great an extent as iron has supplanted wood.

Scientific Progress.

The Moon's Shape.

The moon is the nearest, and next to the sun, the most brilliant of all the heavenly bodies; yet it presents more perplexing problems than any other. Whatever theory has been adopted and however carefully worked out, there are deviations and perplexities which cannot be accounted for or explained.

One of the most difficult puzzles appears to be the strong and somewhat peculiar grasp which the earth has upon the moon, differing quite materially from what it should be if that body was a sphere, or as approximately as the earth is to such a form. If we examine carefully a stereoscopic photograph of the moon—and such pictures are very common—it will be seen that the shape bears a much stronger resemblance to an egg, when viewed endways and looking at the smaller end, than to a sphere. By careful observation it will be perceived that there is a careful rounding away of the body of the moon from its point nearest the earth to a certain distance, when the surface appears to fall away in a nearly straight line. When this plane or surface is tilted by libration, first upon the one side and then upon the other, the true perspective can be readily observed.

This peculiarity in its shape may be accepted as an explanation why one side only of the moon is always turned toward the earth. With its longer axis pointed directly to the earth's center, our planet's grasp upon her satellite is so strong as to admit of a diurnal revolution, conformable only to the moon's revolution around the earth—thus keeping the same face or pole of the moon toward the earth—the only variation from this fixity of position being the slight swinging or pendulum motion of the mass, which is known to astronomers as the "moon's libration."

It is by means of this libration that it has been possible to get a true stereoscopic view of the moon. The artist, instead of moving his instrument to get the stereoscopic effect, waits for the moon to move, the change of motion between the one libration and the other, being sufficient for his purpose. In no other way can this peculiarity of shape be made visible to the eye. Instruments, however perfect, fail in this direction. Proctor says: "It need hardly be said that no instrumental means in our possession can show the ellipticity of the lunar disk."

How this peculiar shape was brought about is explained in the following manner: "When the moon was a molten mass the centrifugal force at the equator was so slight that there was no bulging, but the earth's attraction drew out the mass, lengthening it in the direction of the polar axis, and keeping that axis forever directed towards the earth's center."

Where the Cold Waves Come From.—Meteorological observations have now become so extended that evidence is rapidly accumulating to enable us to determine positively the source of the cold aerial waves which sweep across our country during the winter season. The indications are that we owe them to the great area of high barometer in northeastern Siberia, where the pressure sometimes exceeds 31.50 inches, and the temperature falls as low as 76° below zero. The pole of greatest cold is in the neighborhood of Yokutsk, on the Lena, where the average thermometric reading in January of 41° below zero, and where the severest cold exceeds by 10° that experienced by explorers in high arctic regions. This is also the region of the highest barometric pressure known in winter; and from it, doubtless, proceed the waves of intense cold which play so large a part in our winter experiences.

Fish Killed by Electricity.—A correspondent of *Land and Water* says: A curious incident of the whole of the occupants of a small fish pond being destroyed by a flash of lightning, is reported from Seck, Grand Duchy of Nassau. The *Nassauer Bote* states that during a very heavy thunder and hail storm at night time, a flash of lightning struck a small pond, well stocked with various kinds of fish, the property of the pastor of the parish. The following morning the whole of the fish were discovered dead upon the surface of the water. They had all the appearance of having been half boiled, and crumbled to pieces at the least touch, just as is the case with fish after being boiled. Neither any external nor internal injury could be observed, the scales being intact and the swimming bladder filled and well preserved. The water in the pond was still muddy and dull the morning after the storm, as if the lightning had only then struck it.

Thermo-Electric Steel Tests.—Carl Barus has studied the thermo-electric disposition and the electric conductivity of steel, in their relations to the hardness of the steel. He finds that if a steel rod of uniform known hardness is broken in two and the two original ends connected with a galvanometer, the hardness of pieces of steel can be readily tested. For if the free ends of the test rod are laid on the sample of steel which is to be tested, and either point of contact is heated (*e. g.* with a small jet of steam), the thermo-current will flow from the test-rod if it is harder, and to the rod if it is softer than the sample.—*Wied. Ann.*

Changes in the Appearance of Jupiter.

Writing with reference to the strange belt on Jupiter, in a communication to the *Scientific American*, dated September 28th, Mr. J. A. Brashear, of Pittsburg, Pa., says: "I first saw it at 2:45 A. M. on the 26th of June. A nine-inch silvered glass Newtonian telescope was used in this observation. The belts on the equator were of a beautiful pinkish brown color. The broken belt noticed by your correspondent was so vivid and clear that it reminded me of a coke fire seen on a dark night. It made such an impression on my mind that I at once made a sketch of it, which has been of great value in subsequent observations. In referring to my note book I find I have eight drawings of the planet since the above date. Comparing the last drawing with the previous ones, I am led to believe that the spot has slowly diminished in size, though not in general outline. Another and still more strange phenomenon has occurred, and to this I should like to call the special attention of observers. In my drawings I have located the white spots plainly visible between the equatorial belts, and by comparing the consecutive sketches I find that either the spots or the red belt has shifted in reference to one another about one-fourth the length of the red belt.

"Any one who has read Camille Flammarion's interesting article on Jupiter in the last number of your supplement, will see that this shifting of the spots is no new thing, but the question is, Which belt or spot has shifted? I am inclined to think, with my esteemed friend, Mr. F. W. Very, assistant to Prof. Langley at the Allegheny Observatory, that it may be some terrific action is going on in a local spot beneath the red belt which has dissipated or torn away the vaporous envelope of the planet over the place of local disturbance, and we possibly see the *actual surface of the planet* beneath or through the rift in the vaporous envelope. If this conjecture be true, then it is more than likely that the shifting has been in the white spots beneath the equatorial belts, as the local action which gives us the red belt would hardly be of a shifting character. I have used 6.5-inch, 9-inch and 12-inch aperture silvered glass telescopes, and 4-inch and 13-inch achromatics, at different times of observation, and have had some exquisite views of this marvelous planet and its attendant panoramic phenomena."

Action of Ammonia on Brass.

John Y. McLellan, of Glasgow, writes to the *Chemical News* as follows: While experimenting on the action of liquor ammonia on various metals and alloys, with a view to determine the most suitable for the contraction of a certain part in an ammonia plant, I have met with a reaction on brass which, so far as I know, has not before been recorded, and of which this note is a preliminary notice. If a small piece of brass or a few brass turnings be covered with liquor ammonia, specific gravity 0.880, in a closely-fitting stoppered bottle, and placed aside for a few days, it will be found that the ammonia has acted on the copper of the brass to such an extent as to produce a solution of a more or less characteristic violet color, due to the presence of oxide of copper held in solution by ammonia. If this solution be still allowed to remain undisturbed for a few days longer free from contact with the air, this violet color will gradually disappear, leaving a colorless solution, which, however, is no sooner brought into contact with the air by removing the stopper than the violet color is reproduced, and by again stopping the bottle and leaving it aside the same reaction occurs and may be reproduced over and over again.

The production of the violet color from a colorless solution on exposure to the air does not seem to be the result of oxidation, as on opening the bottle in an atmosphere of carbonic acid the same reaction takes place.

I am at present working up this subject in the hope of finding in what state this colorless solution of copper exists.

Proposed Adoption of the Egyptian Cubit. In noticing the labors of the International Bureau of Weights and Measures, Abbe Moigno regrets the choice, as unit of measure, of the ten-millionth of a meridinal quadrant, "a unit fatally indeterminate," since the meridians vary in length. He suggests, as a better standard, the cubit of the Great Pyramid, which represents the ten-millionth of the earth's polar axis. Sir John Herschel made the same proposal, nearly thirty years ago, and it is somewhat remarkable that his views should be now advocated by a leading French scientific journal.—*Les Mondes.*

The Earth's Day Increasing.—In a recent lecture on "Eclipse Problems," Prof. Charles A. Young, of Princeton, said, with reference to the observed increase in the rapidity of the moon's motion, that the discovery led at first to the opinion that the moon's orbit was growing shorter, and that ultimately the moon would come down upon us. More accurate calculation, however, shows that there is no danger of so disastrous a result. The moon is not coming nearer, but our day is growing longer, owing to the friction of the tides upon the earth's surface. The tides act like a brake, and slowly diminish the speed of the earth's rotation.

Mining Share Market.

In the latter part of last week prices were well sustained, and hopes were entertained by dealers that a buoyant market was opening for them. But in the early part of the present week there was a falling off in values with a marked depression which has not since been wiped out. The fluctuations have not been worthy of note. During this time and at the last session of the Boards there was a very limited demand and the sales were meager.

At the mines there has not been any occurrence worthy of particular notice except that connection was made at noon on the 4th inst. between the north header of the Sutro tunnel and the east crosscut of the Gould & Curry and Best & Belcher 1200 level. The top of the header and the bottom of the crosscut come together.

The extreme cold wave having passed away, it is prohable the hullion shipments will he heavier in the next few weeks.

Assemhlyman Gorley introduced a hill in the Assemhly on the 4th which bears stringently on the wash sales and fictitious operations in the stock hoards, making all such transactions a felony. Also against hrokers hypothecating stocks held by them, helonging to their customers, and to cause them to hold, inviolate, the identical shares left in thcir hands by them. This is a hlow at false sales.

Bullion Shipments.

Since our last issue, we have noticed the following hullion shipments :

Mastadon mill, Dec. 26th, $600 ; Belmont Co., one week, $7,075.51 ; Eureka Co., Jan. 4th, one week, 203,575 pounds; Richmond Con., Jan. 4th, one week, $29,410.56; Agua Fria smelting works, Jan. 6th, 20,000 pounds hase bullion; Silver King, Jan. 8th, 12,000 pounds concentrations; California, Jan. 3d, $105,483.39; Union Con., Jan. 5th, $43,435.21 ; Con. Virginia, Jan 3d, $27,386.57; Northern Belle, Jan. 3d, $9,278.48; Christy, Jan. 5th, $10,231; Alexander, Dec. 29th, $1,802.49 ; Alexander, Dec. 31st, $2,261.81; Alexander, Jan. 2d, $5,788.35; Bodie Con., Jan. 6th, $13,255 ; Ophir, Jan 3d, $27,684.21 ; Northern Belle, Dec. 27th, $11,667,51 ; Northern Belle, Dec. 29th, $6,014.38 ; Northern Belle, Dec. 31st, $8,114.69.

MR. WM. BRUCKNER, well known as an inventor and metallurgist, has received quite a compliment from a foreign source. At a Permanent Exhihition of an Italian society for the promotion of mechanical industries, which is held in Naples, Mr. Bruckner's roasting furnace and ore pulverizer has been on exhihition. The society has awarded him the "Gold Medal for Industrial Merit." These machines are heing made hy an agent of Mr. Bruckner in Milan ; they are also heiug manufactured at Lisle, France.

IT is officially announced that the French vintage is 30,000,000 hectolitres under the average of the last ten years.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

COLD WEATHER.—*Ledger*, Jan. 3: The present cold snap has closed down all the uhining companies at Oleta.

NEW QUARTZ MILL.—The new mill, in Big canyon, of Max Oriffith & Co., will be ready to run inside of the next week.

REPAIRING DITCH.—As soon as the weather changes, so that the works can be run hy the water of Indian creek and the South Fork ditch, the water will be shut off from the big ditch for the purpose of repairing the ditch from the mine to the Middle Fork of the Cosumnes, so as to be ready to commence floating wood and timber down to the mine by Feh. 1st.

QUARTZ CLAIM.—Evans & Co. are prospecting a quartz claim on the north side of Dry creek, one mile above Drytown. The shaft is now down 20 ft, with a ledge two ft thick, which prospects from $12 to $15 per ton.

CONEY MINE.—Retimbering of the Coney mine has been completed to a depth of 450 ft, and two drifts have been started. An additional hoilor will he put up at the mill soon.

NEWTON MINE.—The Newton copper mino is now being worked with renewed vigor, and a number of extra men were put to work a few days ago.

BUTTE.

MINING ITEMS.—*Mercury*, Jan. 2: Now that the rains have made water abundant, we hear of mining being carried on extensively all over the mineral portion of the county. The Spring Valley, at Cherokee, a company that does not depend on the rainstorms for its supply of water, is doing its usual amount of work and presenting to the public the usual number of golden bricks each month. The Hendricks mine, in Morris ravine, will soon be at work in a new place, with most flattering prospects, taking the prospects that are made of the dirt as a criterion. The Big Bar, under the management of John C. Speucer, is proving to be a mine of great value; worth all the money and time spent to put it in its present running condition.

A GOOD PROSPECT.—San Juan *Independent*, Jan. 3: Wm. Ferguson, of Ferguson & Robinson's mine, Butte county, procured from eight pans of dirt about $3 worth of gold, coarse and fine; some of the pieces would weigh over 25 cents. The paus of dirt were taken off the bedrock on ground that had been ground-sluiced. Mr. Ferguson informs us that years ago, when he first worked the ground, he obtained pieces that would weigh over an ounce, and he is hunting for the "pocket" where they came from. We hope it will not be long before he shall discover it.

CALAVERAS.

MINING NOTES.—*Chronicle*, Jan. 3: Work is now progressing in all the gravel mines in this vicinity. The Safe Deposit, Rough Diamond, Green Mountain, Durgan, Boullion, Mammoth, Bonanza, Eureka and Maison de Sante are all running full-handed and pushing things at that. The long-continued cold weather has decreased the water supply somewhat, but it is steadily approaching a maximum again, and the probabilities are decidedly against any further failure from cold this season. The outlook is now decidedly favorable for the mining interest in this portiou of the county. A large quantity of snow has fallen in the mountains and the unusually cold weather we have had recently has frozen it so solidly that it won't thaw out until late next summer. That is a circumstances that presages an abundant water supply until late in the season, and will measurably extend the time that can profitably be devoted to active mining operations. So far as the yield of the gravel mines is concerned reports are extremely favorable.

KERN.

ENTERPRISE GRAVEL MINE.—*Californian*, Jan. 1: Work will be commenced on the Enterprise mine, an extensive gravel claim in the canyon of Kern river, next Monday. Several hundred feet of hydraulic pipe is in position.

MONO.

MINES AT BENTON.—*Bentonian:* That the series of mines of which the Wild Rose is at present the center of attraction are likely to produce a bonanza is not at all improbable. The Wild Rose is down 51 ft and 8 ft in the drift, with no indications of the hanging wall. This is indicative of a wide ledge. The ore is free milling all the way down, and about 75 tons now lie on the dump. A tunnel has been started at the foot of the hill which will tap the ledge at a depth of about 260 ft. Work has been commeneed ou the Nina Rose hy Almon & Smith, and so far as progress has been made the ground shows well. Preparations are being made by Col. Farrington and Capt. Nickelson to at once commence work on the Emma Nickelson, which was the original discovery of the series. On the other claims there has not yet been enough work done to be worthy of mention. A town site, with lots 100 ft square, has been laid off, several houses have been erected, while others are under way, fences have been put up, and taken altogether the place begins to assume the dignity of a camp.

WALNUT.—Bodie *News*, Jan. 1: The Walnut mine has been organized by a company with a capital of $1,000,000. Developments thus far are exceedingly encouraging. Shaft down about 70 ft. Ore sufficient to pay all expenses has been taken out. Ore on the dump averages $64 per ton.

NEW MINES.—Prof. Phillips is putting down shafts in two new mines, near the ledge of the Travcler company's locatiou, for parties in New York.

SOPHIA.—Another New York company has been organized to work the Sophia and other claims. Capital, $50,000, with liherty to increase to $250,000.

MOUNTAIN KING.—The Mountain King shaft is now in over 70 ft. Developments satisfactory. An assay office has beeu estahlished at Richmond, and another at Hot Springs. The sinking of a shaft has been commenced five and half miles from Hot Springs, in a gold and silver claim, by a party from Brooklyn, N. Y. Many strangers are arriving and prospecting over the field. Surveyors are running lines of claims and placing corner posts.

SMELTING WORKS.—The Montgomery County Smelting Company has about finished its works. Blish & Co. are erecting smelting and other works near the Walnut mine. Several permanent buildings are going up at the mines. The climate is very mild, the frost seldom affecting the earth over an inch deep. As yet, very little machinery is in operation. Only two mines have any.

DOUBLE STANDARD.—The east crosscut from the bottom of the winze is now in 66 ft; progress made since last report, 12 ft. There is no change to note in the character of the formation passed through. The north drift from the east crosscut, 200 level, has been run during the week 23 ft, with no change worthy of note in the ledge.

BULWER.—The west crosscut from the south drift, 380 level, has been advanced since last report 10 ft, making a total length of 200 ft. The rock in this crosscut is all very hard. The west crosscut from the bottom of the Ralston winze is in 101 ft; progress made during the week, 11 ft.

SUMMIT.—The shaft has been sunk during the past week 11 ft, making a total depth of 521 ft. The ledge in the bottom is three ft wide, and is looking well. The west crosscut from the south drift, 300 level, is now in 100 ft, with no change to note in the character of the formation.

KING BEE.—Ground was broken yesterday on the new double-compartment shaft of the King Bee mine on Queen Bee hill. The shaft-house is completed, and a contract has been let to sink the shaft 100 ft.

ORIGINAL SUMMIT.—Work on this mine in sinking the shaft is making good progress. The shaft is now 54 ft deep, and the ledge continues of high-grade ore that assays from $75 to $400 per ton.

H. L. & M. C. JOINT TUNNEL.—Mammoth City *Herald*, Dec. 24: The late inclement weather has had no effect on the workings, which have been steadily pushed forward. They have now passed entirely through the conglomerate formation in which they have been working, and are now in solid rock. They are making, on an average, about nine ft per day.

NEVADA.

MT. AUBURN MINE.—*Transcript*: The new hoisting works of the Mt. Auburn quartz mine in this district are completed. It was the intention of Superintendent Kirby to have started the machinery some days ago, but owing to the freezing of the water in the ditch, he was unable to do so.

GODFREY.—Grass Valley *Union*, Dec. 31: The new gravel and cement mill of the Godfrey Gravel mining company will be ready to commence dropping its stamps in a few days.

ROSE HILL LEDGE.—A clean-up of five loads of quartz has just been made from the Rose Hill ledge, which runs through the grounds of the old Marshall place, on Winchester hill, which is now the property of R. D. Lowry. The result was $96.05 per load. The quartz was taken out at a depth of about 30 ft. The ledge, so far, is small, it being about eight inches. Other rock has been takeu out which looks equally as well. There is no water in the shaft to interfere with working and good progress can be made. The lead is being opened by a company of working miners on the tribute plan.

SARGENT & JACOBS' CLAIM.—*Transcript*, Jan. 4: In spite of the extremely cold weather the new hoisting works at Sargent & Jacobs' claim, Quaker hill, has been obliged to stop only once or twice for an hour or so on account of the water that runs the hurdy freezing. The shaft is down 156 ft, and will reach the top of the tunnel in 32 ft more. The hard cement through which it passes requires blasting, and about two feet is sunk per day.

JULIA.—The Julia gold quartz mine, on Deer creek, above the Merrifield and opposite the Providence, will soon be sufficiently developed to demonstrate its true value. After sinking the incline to a depth of 00 ft, and taking out eight or ten tons of fine looking rock, Messrs. Sloan & Dunn, the owners, began to run a tunnel, which has progressed 45 ft, and will tap the ledge within 20 more. Some large holders have been met in pushing the stopel thus far, making the work a little slow. There is a good millsite near the mouth of the tunnel, and plenty of free water can be obtained to run the machinery. The owners express themselves as more than satisfied with their prospects for having a good claim.

MERRIMAC.—*Herald*, Jan. 3: This mine is located on the quarter section just east of the Round Mountain mine. The owners have been prospecting the ground to, ascertain the locality of the ancient river channel. They first sank a shaft down 80 ft and found a strata of gravel on the bedrock, but it contained little or no gold. A tunnel was then run from the bottom of the shaft a distance of 600 ft. Their efforts were rewarded by finding the channel and good pay gravel. The strata reached is from five to six feet thick and prospects richly. The success of this enterprise is of great importance to that promising mining district, as it shows the direction and location of the channel through the mountain. The location of the find is about 500 ft from the line of the Round Mountain claim, and between that claim and the Adalante, thus proving the direction in which the channel strikes the Adalante claim, besides demonstrating that it actually exists there. The deepest portion of the channel has in all probability not been reached yet, as, where the Round Mountain company is at present drifting, the pay gravel is from 12 to 10 ft and deep. The Round Mountain district promises to become lively when the Merrimac and Adalante companies get their mines open and commence drifting.

FLUME ACCIDENT.—*Transcript:* Two sections of the V flume at Snowy Point, above the Red Dog road, broke down Monday afternoon under the weight of ice and snow in the boxes. The damage will be repaired as soon as practicablo.

PLACER.

HIDDEN TREASURE.—*Forum*, Jan. 1: The Hidden Treasure gravel mine, at Sunny South, Placer county, has yielded over $98,000 during the past year, $37,000 of which has been divided into dividends. This is one of the many instances of good paying mines in this part of the State.

MINING INTERESTS.—Our mining interests are assuming greater activity as the season advances, the abundant rains having furnished an ample supply of water for washing. The Polar Star and Southern Cross are both in active operation, employing between 30 and 40 men each and working two shifts. The Franklin claim at present is idle, but the company lutend soon to start a new tunnel at a lower level from Bear river, as the pay dirt is largely below the old tunnel, which is nearly useless unless for working the top dirt. The Lckamp mine is working a small force and so far report a very successful run. A. Larson has several men at work in the Shady Oleu mine extending the tunnel and sinking with good prospects. The Central company are operating in new ground in a different portion of their claim from last season. The ground, it is said, prospects very fair. Other claims operated by individual owners are prosperous, and considering that it is yet early in the season, our hydraulic mines have a very fair start.

STOPPAGE OF WORK.—Owing to the severe cold weather of last week the mines were shut off from their supply of water for washiug. This was a precautionary measure taken to prevent the water from freezing in the ditches if the cold weather continued, which would require work to cut it out or a modifying of the weather to thaw out.

TULARE.

EMPIRE MINE.—The Tulare *Times* says: Hon. Thomas Fowler's Empire mine is all that was expected. The mill is in good working order and bullion is being turned out in good paying quantity.

TUOLUMNE.

HAZEL DELL.—*Independent*, Jan. 3: The Hazel Dell quartz mine, owned by ex-U. S. Assessor Gideon Wing and other parties, is situated in the Enterprise mining district, about eight miles in an easterly direction from Columbia. This property is already attracting the attention of capitalists. The developments alrcady made upon this mine are of so encouraging a nature that active work upon the mine will soon be started.

COLUMBIA.—The mining prospects in and around Columbia, continue most favorable. It is rumored that an important strike has been made in the Shanghai mine, on Yaukee hill, owned by George Morgan, Esq., of the City hotel. A great deal of bullion was taken from this mine in the early days. The Pat Smith, Birney & Hudson claim, on Yankee hill, is developing some remarkably fine prospects.

GEM MILL.—The Gem mill started up a few days ago. Everything is working satisfactorily. The re-opening up of the mine has been the means of discovering new hodies of valuable ore.

ITEM.—Hans Christiansen, the owner of a hydraulic mine, near the county line of Tuolumne and Calaveras counties, was in town on Monday with a pocket full of specimens, one of which was almost pure gold, and worth at least $100. Several other pieces varied in value from $2 50 to $25. It made a good many persons think that the "good old days of Columbia" had come again once more.

NEVADA.

WASHOE DISTRICT.

UNION CON.—Supt's Letter, Jan. 5: We are extracting the usual amount of good-milling ore from our 2400 stopes, which look well, and making preparations to commence the extraction of ore from our 2300 stopes. The Brunswick and Morgau mills are engaged in reducing the ore.

OPHIR.—Supt's Letter, Jan. 5: On our 2500 level the main east drift is in 35 ft from the incline. We shall, during the week, commence excavating for the ore and waste chutes of this level. We shall reach our southern boundary and pass into California ground, from which point that company will run the drift to a connection with the C. & C. shaft. On Monday last we cut into vein porphyry carrying some low-grade ore and the face now shows the same material. We are extracting the usual quantity of good-milling ore from the stopes.

MEXICAN.—Supt's Letter, Jan. 3: We have now 35 ft more to sink before reaching our 2300 level, at which point connection will be made with the drift being run south from the Union shaft by the Union Con. company, and the drift being run north from the Ophir incline by the Ophir company and ourselves.

CON. VIRGINIA.—Supt's Letter, Jan. 3: Since date of last report we have hoisted 1,170 tons of ore. We are making preparations to resume work on the 850 level. On our 1550 level we still continue to extract ore lying to the east of the old stopes. On the 1750 level the work of repairing No. 1 winze is completed, and we have commenced to extract ore at that point.

CALIFORNIA.—Supt's Letter, Jan. 5: During the past week we have extracted 1,225 tons of ore. On the 1750 level we are still engaged in stoping out ore from the north ore body. The raise from crossent No. 8 is now up 114 ft on the slope. This raise will be connected with the 1050 level some time during the coming week. This will form a direct connection with the Con. Virginia shaft and materially improve the ventilation of this portion of the mine.

SILVER HILL.—Supt's Letter, Jan. 5: We have ordered a Baker blower, which will he here about the 10th of next month. The Ophir compauy have a uow one, not in use, which they will let us have immediately and take ours when it comes. This accommodation will give us a good supply of fresh air in a few days.

HALE & NORCROSS.—Supt's Letter, Jan. 8: The air connection from 2100 to 2200 levels, through north winze, has been made, and the ventilation much improved. Our pumps are working splendidly, making over 10,000 strokes per day.

OVERMAN.—A crosscut has been started from a point in the 1000 north drift 180 ft from the Belcher. This is about 20 ft south of the south line of Segregated Belcher.

BELMONT DISTRICT.

BRIGHTER.—Times are considerably brighter in Belmont than they have been for a long time past. The Belmont company are running 10 stamps, and made their first bullion shipment last week. The company are daily putting new men into their mine, and it is understood that 10 more stamps are to be started soon.

ALEXANDER.—Belmont *Courier*, Jan. 4: This mine is ono of the best in eastern Nevada. There is au immense amount of good milling ore in sight, enough to keep three or four 20-stamp mills running for years. The new crusher will be started up some time in January, and if it proves a success the bullion output of the Alexander will he quadrupled.

EUREKA DISTRICT.

PROGRESS IN THE K K.—Eureka *Sentinel*, Jan. 3: During 1879, about $80,000 was spent in developing the K K. The main shaft was sunk 200 ft, two new levels were opened, and considerable prospecting done on another. Oro has been found on the eighth level within the past week, and it is said that ore hodies are now uncovered in all the levels in the mine. For the current week, about $7,000 worth of ore bas been shipped to the Richmond, and more will shortly follow. The last assessment was sufficient to pay all debts, including one which has been hanging over the company for some time, and should another be levied, the money will he used in developing the mine. At no period in its existence has the K K looked hetter.

CONNOLLY.—Mr. M. P. Murphy has leased the lower levels of the Connolly mine from Mr. John A. Potter, the Superintendent, and will immediately proceed to develop it.

SILVERADO DISTRICT.

THE QUEEN.—Eureka *Sentinel*, Jan. 4: Tho Queen mine is ono of the best little mines in the State. Its ores are of high grade, and the owners have always worked the mine at a fair profit. Just now four men are engaged who extract about $100 per day. The ore ranges from $150 to $800 per ton. It is usually treated at the Richmond.

ARIZONA.

BRADSHAW ITEMS.—*Arizonian*, Dec. 26: The Tiger mine has been sold to a New York party. The Oro Bonito has been sold to a San Francisco party, who has taken charge of it. The Goodwin is a splendid ledge. The Del Pasco mill is ready to run. The Bowen saw-mill is running; quartz mill not yet started. Frank Ryland has again started his arastras to grinding rock from the Southern Belle. It paid him $50 per ton before water gave out last summer.

MINING ITEMS.—Cave Canyon district, in the Huachucas, sends in the most favorable reports of the richness of its mines, which average from $150 to $800 per ton. E. N. Fish and others, of Tucson, contemplate reopening the old Mowry mines, seven miles south of Patagonia. Washington camp, near the Sonora line, is developing a fine lot of carbonate smelting ores of average value of $50 per ton, with ledges ranging in width from 1 to 150 ft. Another rich mining section is being attended to in Pinal county, Mineral Hill, 14 miles from Florence.

TOMBSTONE ITEMS.—*Citizen*, Dec. 27: The Grand Central mine, at a depth of 175 ft, has some very rich ore, some beautiful samples of which are in town. Assays run very high. The Contention people are still taking out their chlorides and getting ready for operatious at the new mill. The Rattlesnake, south of the Grand Central, has a shaft down 70 ft on a very strong ledge, and are now in solid ore. They have the footwall, but, as yet, have not found the hanging wall. The oro is of the samo general character as the Contention and Grand Central. Mr. A. J. Mitchell and others are owners, and the property is now bonded for $75,000. The Emerald, near the Rattlesnake, was recently purchased by Messrs. Marks and Goldtree. The owners intend to sink a shaft at once and properly develop the mine. The same parties have begun work on the Blue Jacket, which shows a fine ledge of ore averaging about $125 per ton. They also own an interest in the Way Up mine, on which they will sink a 50-ft shaft. Work is progressing on the Head Center mine with good results. The new owners have started up again on the Empire mine, and have a fine body of ore. The Corbin mill will be ready for ore soon after Jan. 1st, and the Contention expects to start up about a month later. The Corbin mill will work custom ore.

COPPER LEADS.—*Nugget*, Dec. 25: A new feature is springing up in the Huachuca mountains, in the copper leads which abound in that range. Marks & Co., who own some claims in what is known as the Miller and Mormon canyon, have been offered and given a bond for $80,000. The ore gives an assay of 40% copper and from $230 to $250 per ton in silver. The near approach of the railroad is opening a market for the valuable copper leads in the Huachuca mountains.

PATAGONIA ITEMS.—Tucson *Star*, Dec. 25: Ore has been struck in Protection tunnel at a distance of 270 ft. This is supposed to be the south veiu of the Hermosa. Another contract has been let. The W. C. Davis mine has been sold to San Francisco parties for $45,000. The Hardshell still continues to uncover fine hodies of ore D. Gillette has put a force of men to work on the mill site, grading and opening up the water courses. Some very rich discoveries have been made on the north side of Mowery hill, these fine claims showing good ore. A new town has sprung up at the old Patagonia mine, and it is christened Mowery. There is an assay office run by Bragg. Washington camp is coming to the front. The camp is located three miles south of Mowery. Mr. Allen is putting up a good hotel.

HERMOSA.—Pima *Record*, Dec. 25: In the south tunnel of the Hermosa exceedingly rich ore has been struck, about 300 ft in, of same quality as that in the main shaft. There has been some talk about the Hermosa having "petered." If these doubters would visit the mine now, and examine recent developments, they would be more than satisfied of the great value of this property. The deepest shaft is about 75 ft. A piece of ore from this

CONTINUED ON PAGE 28.

On the Origin of the Leadville Ore Deposits.

All through the Leadville ore district limestone is universally recognized to be the bedrock of carbonate formation, and limestone being, therefore, the strata underlying our subject—its foundation, as it were—it is with that I begin.

This limestone was deposited at a time when atmospheric and terrestrial conditions were totally dissimilar to those of the present day. The formation of the minute crystals of calcite and dolomite that unite in building up limestone does not in general take place through the simple secretion of the carbonates of lime and magnesia from the bicarbonates of these earths that are held in solution in sea water, because none of the conditions are given under which their secretion from the solution could take place. Where springs occur that deposit lime, it is on account of the evaporation of water and volatilization of the carbonic acid that the carbonate of lime is secreted. Seventy-five per cent of the water of our present seas would have to evaporate, however, before a deposit of limestone could be formed, a process only to be thought of as possible in the case of an inland sea or at the mouths of large rivers. These latter spread their waters, containing the bicarbonate of lime and magnesia, on the surface of the ocean, whose waters are specifically heavier in consequence of the percentage of salts, and are here exposed on the one hand to the influence of the sun's heat, on the other to that of hurrowing winds, whereby an evaporation of part of the water as well as of carbonic acid is facilitated, and the formation of carbonate of lime is made possible.

A similar process took place, on a far greater scale, however, in the oceans of the oldest geologic periods. At that time, the atmospheric precipitations were richer in carbonic acid than at present, as they had to traverse an atmosphere in which was diffused the whole of the carbonic acid which has since been incorporated with the earth, in the carbonate rocks, as such, in the plants, and in the carboniferous formations. These rainfalls, rich in carbonic acid, acted on the lime and magnesia silicates of the then existing rocks, decomposing them and conducting strongly concentrated solutions of lime and magnesia carbonates to the sea. The final degree of concentration was reached on the surface of the ocean, and the carbonates of limes and magnesia were deposited in the form of dolomitic limestone.

On top of this limestone was deposited locally, and in varying thickness, carbonate of iron. The formation of carbonate of iron is not possible where air can get at it; therefore, it must have taken place at a time when this valley was covered by the sea. If air were present, so rapid is the change from the protoxide of iron to the hydrate, that hydrated carbonate of iron would have been formed.

Now, after all this lime and iron had been deposited, there ensued a period of volcanic activity. Huge masses of porphyry were poured out of the craters, covering the iron and newly-formed limestones with immense masses of rock, the eruption being partly submarine in character. During this outflow of porphyritic lava, a general upheaval of the country took place, and the sea that covered it, receding, poured its flood eastward. After the first eruption, the land again subsided for a sufficient length of time to allow of another deposit of iron and lime being formed, whereupon once more porphyry was ejected in immense quantities, covering the beds of limestone and iron with fresh masses of eruptive rock. This change took place several times, forming thus the different contacts between lime and porphyry that have been met with in this district.

The gradual dying out of volcanic action was accompanied by the usual disturbances. Earthquakes occurred, rending the rock into huge fissures, from which exuded thermal springs, holding different minerals in solution, and, as was probably the case, these fissures were opened again and again. Fissures do not assume their present dimensions from the beginning, but were originally narrow clefts which were partially widened; indeed, fissures that were already formed and filled with vein-material were subject to frequently-repeated openings, which can be easily explained if the slow and gradual action of the upheaval is taken into account. If the fissures were already cemented together by gangue rock, and a new tearing-open of the vein took place, it was refilled, and in that way widened.

Now, the fissures would naturally be formed where the least resistance would be encountered, which, in this case, would be along the planes of contact between porphyry and lime. It is very probable, however, that the fissures did not always adhere strictly to the contact planes between porphyry and lime; indeed, the evidence goes to prove that, in certain places, the volcanic agency, not content with forming fissures along the planes of contact between porphyry and lime, made huge rents in the solid rock itself. Subterranean waters, seeking an outlet to the earth's surface, took advantage of these fissures, and appeared under the guise of hot springs.

The rare and very slight percentage of alkalies contained in most ore-veins is noticeable, and as a distinguishing feature, stands in marked contrast with the eruptive rock, whereas the country rock, where it contained alkalies, has, for the most part, lost them in the neighborhood of the vein. They have been dissolved and carried off in the form of solutions, while other substances have been deposited in their place. In other words, the dissolving of the alkalies has reacted on and furthered the precipitation of the vein minerals; and it is therefore not to be wondered at, if veins have frequently been found to be richer when passing through decomposed rock.

Principally water, in conjunction, perhaps, with different gases, was the medium which collected the diffused particles of the metals and other substances, and deposited them by gradual processes in a far more concentrated form than before. It is known that, in the majority of veins, the gangue material has either come from the neighboring rocks or from deeper regions below.

We have now, therefore, these thermal waters circulating along the fissures, which are filled with carbonate of iron. These waters contain, besides oxygen, lead, silver and other minerals in solution. All substances, therefore, which unite with oxygen become oxidized when brought in contact with such waters. Thus, the oxygen, attacking the carbonate of iron, frees the carbonic acid and, with the help of water, changes it to hematite; the lead, containing most of the silver, is deposited in the form of galena or sulphuret of lead. It is a well-known fact that all metallic sulphurets are subject to a gradual process of oxidation in the presence of water containing oxygen, such as we have supposed to be circulating along this fissure; therefore, most of the galena would naturally be oxidized to lead-vitriol or anglesite. Metallic carbonates are frequently formed by the decomposition of the metallic sulphates, through the action of water containing carbonates of alkalies or alkaline earths (said sulphates resulting from the oxidation of the metallic sulphurets). In this case, the carbonic acid of the iron, freed by the oxygen of the circulating waters, attacks in its turn the sulphate of lead, changing it to cerusite, unites with the alkalies held in solution in the water, and deposits of lime are formed, a certain quantity of the acid escaping in gas form. The sulphuric acid, derived from the decomposition of the metallic sulphates, connects also with the alkalies of the water and is carried off in solution.

The chemical processes involved in these changes can be clearly shown in the following formulæ:

$$Pb.S + O_4 = PbO.So_3.$$
$$PbO.SO_3 + CO_2 = PbO.CO_2 + SO_3.$$

The lead ores galena and cerusite, carrying the greater part of the silver, form the body of the vein, but are also generally finely disseminated throughout the iron ore. The occurrence of chlorides and bromides of silver in some localities attests the superincumbent presence of the sea during the formation of the vein minerals.

Thus we have our veins, which were originally deposits, filled with hematites that contain some of the silver, lead ores that contain the rest, and spring water charged with carbonic acid. The volcanic activity decreased gradually and finally died out, leaving a few feeble soda springs in the surrounding country to attest its former greatness.

Ages passed, and erosion began its work. The land was carved out, by the agency of wind and water, to its present form; then followed the glacial period, covering the greater part of the country with varying thicknesses of boulder drift, rounding all the foothills, and leaving incontestable evidence of its existence in the terraces so frequently met with lower down, in the valley of the Arkansas. Finally, the mountains, hills, and valleys were hidden from view by a dense growth of spruce and pine forests, an impenetrable veil not to be lifted, until man, in his eager search for gold, disclosed the more modest, perhaps, but certainly more valuable and lasting deposits of silver, upon which were founded the future prosperity and greatness of the city of Leadville.—*F. M. Amelung, in Engineering and Mining Journal.*

Clean-up.—From a letter written by J. C. Franck, of French Gulch, to John Louden, of Reading, we learn that John and Ignatz Franck have cleaned up again, and that out of 31 tons of rock they got $1,850. This is a fitting reward for the enterprising owners, and we congratulate them upon their success. French Gulch is very rich in quartz, and with the assistance of the hardy sons of toil residing there, will add materially to the wealth of Shasta county.—*Reading Independent.*

Since January, 1878, the Argenta Company has shipped bullion valued at $85,798.52. This shipment is the result of less than two months' milling. A dividend of $20,000 has been paid during the year, and no assessments have been levied upon the stock. About the 1st of next month the company will take charge of the Grand Prize 20-stamp mill, and will probably run it on ore from the mine during the winter.—*Tuscarora Times.*

The Furguson mine is keeping up its lick. The result of six and a half days' run, crushing 60 tons, brought to town Wednesday, was $1,400. Yield for month thus far, $3,331, which will be materially added to by the close of the month.—*Sonora Democrat*, Dec. 27th.

From all information, it is safely assumed that the annual consumption in the United States of precious metals in all form for manufacturing purposes, now averages $7,000,000 of gold and $5,000,000 of silver.

New Mines in Inyo.

Situated in a detached spur of mountains just to the northward of Deep Spring valley, and but a few miles distant from Piper's ranch in Fish Lake valley, are two ledges of gold and silver-bearing quartz. The ledges are about a mile or less apart, and run in a northeast and southwest direction, parallel to each other and also to the axis of the mountain. These are the locations in question. The most westerly, which has an elevation of some 500 feet greater than the other, is designated as the Great Mogul. It crops out boldly from four to ten feet wide, for full one-quarter of a mile in length. Specimens from various portions of croppings from end to end are so nearly alike in general appearance as to be quite undistinguishable as being from different parts of the lode. This uniformity in general appearance is quite as well sustained in assay values. It appears that it is hardly possible to find a piece of rock larger than a man's fist but makes a goodly and quite uniform display of both chlorides and sulphurets of silver, the former rather predominating. Following are the figures of two assays made recently: No. 1—Gold, $14; silver, $103.67; total, $117.67. No. 2—Gold, $14.50; silver, $95.50; total, $109.50. The other lode is still more of a wonder in various ways. Its average width is about six feet, perhaps more as an average, since it widens to 25 or 30 feet. There are no less than five different locations, each of 1,500 feet, all marked in continuous length by the plainly visible croppings. In this distance it is cut down and exposed at one point by a narrow gulch to a depth of from 1,200 to 1,500 feet below the highest points of the same croppings on the adjacent mountain side. Throughout this great distance the uniformity in appearance and assay value of the ore is nearly as well sustained as in the first mentioned. This lode, as a whole, is known as the Great Eastern, and the several claims respectively as the Great Western, the Horton, the Whiteman, the Thanksgiving and the Eastern. There is a stream of running water about a quarter of a mile distant from one point of this lode and plenty of wood about three miles distant. Assays made at the same time as the above resulted as follows: One from the Horton—gold, $12.55; silver, $51.83; total, $64.38. One from the Thanksgiving—gold, $50; silver, $337.33; total, $387.73.—*Inyo Independent.*

Prevention of Overwinding.

Mr. R. Cottex, of Virginia City, gives to the *Enterprise* the following description of the working of a device he has patented for the prevention of overwinding of cables of hoisting works:

This device is to shut off the steam at a proper depth in the shaft, by the action of the cage as it ascends, and to set the brake when the cage rises two or three feet above the landing. The steam valve and brake are operated on by means of trips and weights. The steam may be shut off at any depth required in the shaft, by placing the trip for that purpose at the desired depth. I think it should be placed so low in the shaft that when hoisting about half a load, or a small load of men, the cage, when running at ordinary speed, will just come above the landing; then, if the brake is good and the gallows frame is of ordinary hight, there is but little danger of running into the sheaves. In hoisting full loads, after the speed has slacked, if the cage does not come above the landing, the engineer can turn on the steam again to bring up the load, as he does not at any time lose control of the steam valve, and he need not set the weight until after landing the cage. The engineer should always shut the steam off before the cage strikes the trip in the shaft; then, in case he is away from the steam valve, or negligent in his duty, it will shut the steam off for him. The portion of this device for shutting off the steam operates every time that the cage passes the trip in the shaft when it is ascending, and the engineer cannot hoist the second time without setting the weight or knowing that it is not set, for when he turns on the steam to hoist again if it is not set, the weight will be banging on the valve or lever. It takes but a second or two to set the weight, and the engineer can set it at any time after landing his cage before starting up again. The trip for setting the brake should be placed high enough on the gallows frame to give the engineer sufficient room for landing his cage without touching it. As it is only intended to be used when the cage goes too high, it does not interfere with working other brakes, and a competent engineer may run for several months without bringing it into action. When he does it is very easily set again. It can be built very powerful, and if the brake is good will hold more than the engine can hoist. My patent makes no claim to the brake or steam valve. It is intended to be applied to those now in use with as little expense as possible, but the better they are the better it will operate. In connection with this statement, I wish to say in reply to some objections I have heard to these devices: First, it is said by some that they have a tendency to make the engineer careless, and I have no doubt but some of them have; but in regard to this device, I can say on the authority of some of the engineers who have used it for about eighteen months, that it is inclined to make the engineer careful instead of careless, for if he does not shut off the steam at the proper place, it will not only shut it off for him, but it will also give his arm such a jerk that he will recollect it for some time. One of them remarked to me not long ago that it was "the darndest quickest thing to wake a man up he ever saw; if he was drowsy or sleepy it would give him such a jerk that it would bring him to his senses in no time." Secondly, I have heard it said they can turn on a full head of steam and let the engine go when coming up loaded, but they cannot when coming up empty. To this I can say that they can by shutting the steam off low enough in the shaft, but is best not to shut it off so low, for an engineer is not likely to turn on a full head of steam when coming up without a load and let his engine go; and, again, if the steam is shut off too low, the engineer, when hoisting loads, must turn it on again and hold the valve open with the weight hanging on it until he brings his load to the top. The steam should be shut off low enough in the shaft to prevent running into the sheaves when running at ordinary speed, with or without a load.

I make this statement for the benefit of all interested, and hope it will be copied by the papers of mining towns in general.

Reworking an Old Mine.

The Placer *Argus* has the following to say concerning work going on near Bloomer cut: J. S. Morris, G. C. Price and J. M. Brooks, having obtained control of the old Decker mine, below Bloomer cut, part of it by purchase and part by lease, began working the same Sept. 3d in good style. Fifteen men are employed there at present, working in three shifts of eight hours each, which arrangement is found better than the working of two ten-hour shifts would be. The place has assumed every appearance of a lively little camp. The mine has lain idle for about 15 years, with the exception of $100 worth of assessment done yearly to maintain title. The old shaft, which was down 65 feet, has been cleaned out by means of a Hammond water lifter and one of Gregory's patent steam pumps. Thirty tons of rock have recently been sent to Pugh's mill to be crushed, and satisfactory results are confidently anticipated. The shaft is covered by a substantial building, the dimensions of which are 28x30 feet A boarding-house and blacksmith shop have been erected; a stable is being put up, and the building of another dwelling-house will be begun next week. The claim is 1,500 feet in length, and 100 feet on each side of the ledge. They have also taken up the eastern extension of 1,500 feet more, and are sinking a second shaft thereon. An old car, which had been covered up in the shaft for 18 years, was excavated the other day, and that, together with the timbers, was found to be in a first-rate state of preservation.

The Engineer.

Report of the State Engineer.

A writer for the *Call* has secured some hints in advance concerning a forthcoming report, which we give for what they may be worth: State Engineer Wm. H. Hall is at work upon his report to the Legislature upon "providing a system of irrigation, promoting rapid drainage and improving the navigation of the Sacramento and San Joaquin rivers." The report will be submitted this week, and will be a very elaborate document, containing exhaustive arguments on the problems of irrigating plains, the condition and capacity of the drainage lines of the State, the improvement of the navigation of rivers, the relation which hydraulic mining bears to the navigation of rivers, the amount and value of agricultural land injured, and suggesting a plan whereby such injuries may be averted, with deductions and recommendations in regard to the principles which ought to govern in the irrigation of lands, and the relief of the rivers when in flood. In reference to irrigation, Mr. Hall endeavors to solve the following problems: The position and acreage of lands in the valleys of the State which are now, or may in the future be, in need of irrigation, and divide them into natural districts; to ascertain the water sources from which each district may be most conveniently irrigated; the quantity and length of time of the supply, with details of the best means for irrigating each district; how the irrigation of land has been accomplished, and at what cost; the processes of irrigation and their results, showing the progress made in developing agriculture and affecting property values, tax returns, and the capacity of the land to support population—pointing out the comparative values of irrigation and dry farming in different portions of the State. Under the head of "Conditions and capacity of the drainage lines of the State," Mr. Hall gives the extent and location of lands subject to overflow by the San Joaquin and Sacramento rivers and their tributaries; the characteristics with regard to topographical configuration and subsoil of the swamps; the nature of the floods, and whence and how they come; the method of draining and reclaiming them, with suggested improvements, and their cost, pointing out the climatic changes resulting from reclamation of swamps, and its effect on navigation; showing the present outlook and drawbacks, and pointing out what should be the true policy of the State and General Government toward the whole subject-matter. In relation to improvement of the navigation of rivers, Mr. Hall says: "The importance and great value of internal commerce by means of free and roomy highways therefor, upon the internal water-courses of a

country, is too generally recognized for this subject to give rise to any questions which may properly be designated as problems, other than those of a purely engineering nature—those respecting the methods of improving the channels themselves, or preventing the navigation of them from being injured; there being no question as to the opinion that it were good policy so to do." In considering the preceding questions, Mr. Hall discusses what he calls "political problems", or "questioue" which are presented in the consideration of ways and means to adopt in systematizing the distribution of the waters of the streems of the State, so that the greatest good may accrue to the greatest number, from the benefits to be derived from irrigation, are properly political problems.

There are legal points, financial and business considerations, and social questions involved in this class of "problems." An exhaustive history is given of the past and present navigation and condition of the streams, and the causes to which present conditions are attributed; works of the past, designed for improving navigation, and their effect; the danger from material injury in the future, and what preventive measures should be employed to counteract or arrest the evil. The "effects of hydraulic mining" are dwelt upon at length, and the proportion of debris transported by the rivers from hydraulic mines is given; also, its effect upon the stream in its carrying capacity and the elevation of flood waters; the injuries to agricultural land by the product of washings being deposited thereon; the proportion of debris carried by rivers from quartz and placer mines, and other sources, with proposed remedial measures, and concluding with a statement of the relative importance of mining and agricultural interests, and how the latter is threatened with serious injury by debris deposits.

According to the terms of the act, which was approved March 29, 1879, "The Governor is authorized to employ, for the purpose of advising and assisting the State Engineer, two consulting engineers, who shall receive $3,000 a year each." Col. Mendell and Gen. Alexander, of the U. S. Engineer Corps, were appointed consulting engineers by Gov. Irwin. Gen. Alexander died, however, and Capt. Eads, who was engineer of the Mississippi River bridge, etc., was appointed to the vacancy, but is now in Europe, and will not return in time to be consulted prior to submitting the report. An appropriation of $100,000 was made to defray the expenses of the operation. The State Engineer gets $6,000 a year. The act under which he was appointed is closely allied to that creating the Sacramento River Drainage District, and establishing a Board of Commissioners therefor. Col. I. W. Smith was appointed Chief Engineer of the latter, and reported against the feasibility and effectiveness of building the proposed canal from Knight's Landing to Suisun bay, whereby it was hoped the Sacramento might be reduced during flood seasons. For this work an appropriation of $10,000 was made.

Railway Construction in 1879.

The *Railway Age* has an article reviewing the progress of railway construction during the last year. It says that the past year has been an extraordinary one in respect to the revival of railway building, more miles of track having been laid than in any year since 1873, and probably more than in that year. We quote as follows: The returns, of course, are not yet all in, but from various sources of information we have compiled the following table showing the total mileage constructed in each State, so far as we are able to learn, reserving the opportunity to a detailed statement with additions:

	Broad gauge.	Narrow gauge.	Total.
Arizona	153	—	153
Arkansas	—	9	9
Colorado	7	00	07
Dakota	220	—	220
Georgia	10	25	35
Illinois	90	—	90
Indiana	74	40½	114½
Iowa	325	40	371
Idaho	—	00	00
Kansas	498	—	498
Kentucky	05	—	65
Louisiana	65	—	65
Maine	—	18	18
Maryland	18	—	18
Massachusetts	11	—	11
Michigan	12	41½	53½
Minnesota	394	—	394
Missouri	101	27	188
Nebraska	125	—	125
Nevada	—	35	35
New Jersey	4	—	4
New Mexico	125	—	125
North Carolina	25	—	25
New York	67½	6	73½
New Hampshire	—	0½	0½
Ohio	105	108½	213½
Oregon	30	—	30
Pennsylvania	14	5	10
South Carolina	—	2	2
Tennessee	119	57	176
Texas	120	67½	187½
Utah	83	46	129
Virginia	20½	—	20½
West Virginia	—	20	20
Wisconsin	00	15	75
Total	3,010	728½	3,738½

It will be noted that the greatest amount of tracklaying has been done in Kansas, which shows nearly 500 miles of new roads, while Minnesota follows with 394, Iowa with 371, young Dakota with 220 and old Ohio with 213½, and so on.

It is also notable that nearly one-quarter of the total mileage—at least 728 miles—is of narrow gauge, showing that the narrow-gange "delusion," as some call it, has not yet run its course.

Useful Information.

How the Ancients Engraved Gems.

A writer in *Harper's Magazine* for September says: We must remain as yet some little in doubt as to the methods employed by the old artists to perfect these miracles of taste. We have, however, the absolute certainty that these ancient masters were familiar with the diamond, and that their best work was made by using this, the hardest of all substances, as a tool. A splinterad fragment of the diamond served as a scraping tool, and they were well acquainted with the drill. Prehistoric men worked a drill at the very commencement of his existence. A Phœnician gem—a lion attacking a bull—shows how the drill was used. A number of circular depressions are found in the gem which mark the extremities of the figures. This was done not for the sake of effect, but to show the artist the limit of his work as to depth. After the holes were sunk, the artist united the various portions of his work by scratching. Now the use of the diamond point or spluter, fixed in a style of iron socket, allowed a certain flexibility of handling which our modern processes of gem-engraving do not permit.

To-day the work is done by means of a minute rotating disc of copper, which is whetted with oil and diamond dust. On the least application of the substances to be cut to the disc, it is the disc which bites into the stone. The difference of manipulation is, then, that to-day it is the stone which goes to the tool, and not, as in olden times, the tool to the stone. It is more convenient, then, in 1879, to bring the cart to the horse. It can now be readily understood why, in modern work, time and labor being spared (the art-conception not entering for the present into the subject), why this work of to-day is inferior to the art which is past. It is purely a mechanical process now, for a rotating disc will no more draw lines which have feeling than will photographing processes paint pictures. It has been stated that we are not entirely acquainted with the methods employed by the old glyptic artists. This becomes quite evident from this fact, that their best work seems to have been both cut and polished at one and the same time. To-day we have no tool, no substance which will accomplish this double feat. Mr. King, dwelling on the diamond point, says: "Its extensive use is the great distinction between the antique and modern work."

"Jannin's Cement," a recently patented French product, named after its inventor, is simply composed of a mixture in suitable proportions of yellow oxide of lead—that known in trade as "Massicot" is preferred—and glycerine; other metallic oxides and coloring matter may be added to the above mixtures, according to the character or color that may be desired. The cement may be made to possess more or less stiffness by varying the proportions of glycerine—the larger the percentage of the latter, the softer the cement, and *vice versa*. This cement is represented to be especially adapted for molding objects which demand an extreme delicacy in the lines of the cast, such as engraved blocks and plates, forms of printing type, photoglyptic plates, etc. It is affirmed that it sets in a few minutes under the influence of a gentle heat and then admirably resists heat and pressure. When set, it is said to make a good substitute for lithographic stone. It is also recommended for artistic reproductions, such as fac similes of terra cotta, the color and sonorousness of which it closely imitates. It does not shrink in setting. So says the *English Mechanic*.

Vegetable Dyes from Cabbage.—MM. Savigny and Colineau have just made a discovery of considerable practical importance in obtaining harmless colors from this vegetable. They have succeeded in extracting from red cabbage, or broccoli, a coloring matter which is absolutely inoffensive, and capable of application in all the ordinary operations of painting, printing and dyeing. To this they have given the name *cauline*, from the Latin *caulis*, a cabbage. The leaves of the plant are cut into small pieces, thrown into boiling water in the proportion of 3 lbs. of the leaf to 3 liters of water, and there left to macerate for 24 hours; at the end of this time they are withdrawn and subjected to a strong pressure, and the juices thus expressed are added to the liquor of infusion. As thus obtained, the "cauline" is of a blue-violet color, and forms the base of a series of derivatives of various colors.

Repeating Matches.—A patent has been taken out for a repeating match—that is, a match that may be struck a great many times, and yield a light each time. The match consists of two rods of inflammable composition, placed side by side in two compartments, with a suitable case. In order to strike the light, a scraper is moved by hand along a platform across the open ends of the two rods. The scraper removes a certain quantity of its enhstance from each rod, and mixing these together, the light is produced. One stick is composed of three parts chlorate of potash and one part of clay, thoroughly mixed and formed into a thick paste by the addition of water, then dried. The other stick is made of three parts amorphous phosphorus and one part of clay, prepared in the same manner.

Household Perils.

Under this head the Boston *Journal of Chemistry* names several dangerous substances which find their way into households. There are two or three volatile liquids used in families which are particularly dangerous, and must be employed, if at all, with special care. Benzine, ether and strong ammonia constitute this class of agents. The two first named liquids are employed in cleansing gloves and other wearing apparel, and in removing oil stains from carpets, curtains, etc. The liquids are highly volatile, and flash into vapor so soon as the cork of the vial containing them is removed. Their vapors are very combustible, and will inflame at long distance from ignited candles or gas flames, and consequently they should never be used in the evening when the house is lighted. Explosions of a very dangerous nature will occur if the vapor of these liquids is permitted to escape into the room in considerable quantity. In view of the great hazard of handling these liquids, cautious housekeepers will not allow them to be brought into their dwellings, and this course is commendable.

As regards ammonia, or water of ammonia, it is a very powerful agent, especially the stronger kinds sold by druggists. An accident in its use has recently come under our notice, in which a young lady lost her life from taking a few drops through mistake. Breathing the gas under certain circumstances causes serious harm to the lungs and membranes of the mouth and nose. It is an agent much used at the present time for cleansing purposes, and it is unobjectionable if proper care is used in its employment. The vials holding it should be kept apart from others containing medicines, etc., and rubber stoppers to the vials should be used.

Oxalic acid is considerably employed in families for cleaning brass and copper utensils. This substance is highly poisonous, and must be kept and used with great caution. In crystalline structure it closely resembles sulphate of magnesia or epsom salts, and therefore frequent mistakes are made and lives lost. Every agent which goes into families among inexperienced persons should be kept in a safe place and labeled properly and used with care.

Weight of Different Minerals.—The following shows the weight (avoirdupois) per cubic foot of various kinds of material: Average mortar, 106 pounds; loose earth, 95 pounds; common soil (compact), 124 pounds; clay (compact), about 135 pounds; clay with stones, 160 pounds; brick, 125 pounds; lead, 709 pounds; wrought iron, 481 pounds; cast iron, 450 pounds; lime, 64 pounds; sand (loose), 96 pounds. And the following shows the bulk of one ton of different substances in cubic feet: earth (compact), 18; earth (loose), 32 cubic feet.

To Destroy Bugs and Fleas.—This mixture, which has been patented in France, consists of 80 parts of bisulphide of carbon and 20 parts of essence of petroleum.

Good Health.

The Sanitary Virtues of the Eucalyptus and the Pine.

At a recent meeting of the Social Science Congress, at Manchester, England, Mr. C. T. Kingzett read an interesting paper on the subject of the above title before the health section of that body. He referred to the old theory that the admitted sanitary powers of the "fever-tree" were due to its drainage properties, and held that this hypothesis lacked evidence, and even at its best was of a negative character. He argued that the superiority of the eucalyptus as a means of drainage would be measured by the proportion in which its rate of growth exceeds that of other trees, and affirmed that this was quite inadequate to account for its extraordinary fever-destroying properties. Other trees planted in malarial districts do not free them from the disease, from which, the author infers, the action of the eucalyptus is of a positive type.

The conclusion to which he comes is that the eucalyptus, and also the pine, exert a beneficial influence in virtue of the volatile emanations arising from them. He finds that the *Eucalyptus amygdalina* yields from 3 to 6 pounds of oil from 100 pounds of its leaves; and that this oil is practically identical in composition with the oil of turpentine derived from pine trees, and with most of the so-called essential oils or perfumes. These oils, when submitted to the action of atmospheric oxygen and moisture, produce peroxide of hydrogen and a number of camphoraceous substances having decided antiseptic properties.

He makes a calculation to show the enormous amount of these emanations. Taking, for example, New South Wales and South Australia, he shows that the eucalyptus forests of these districts contain, at any given moment, sufficient oil in their leaves (ready to be given off into the atmosphere by the agency of warm winds) to form by contact with the atmosphere over 92,000,000 tons of peroxide of hydrogen, and over 507,000,000 tons of camphoraceous principles. From the exalted oxidizing power of peroxide of hydrogen, which greatly exceeds that of ordinary oxygen, and the readiness with which substances of animal and vegetable origin are oxidized, and from the well-known antiseptic properties of the camphoraceous substances above named, Mr. Kingzett concludes that the sanitary virtues of the eucalyptus must, without doubt, be ascribed to the active chemical operation of its emenations. What is true of the eucalyptus must also be true of the pine, and on an immensely larger scale, since pine forests are widely distributed over both hemispheres, and the oil of turpentine, which is a natural product of the pine, undergoes the same chemical changes in the atmosphere as the oil of eucalyptus.

Why Gold in Jewelry Changes Color.—It is well known that the human body contains humore and acids, similar in action to, and having a like tendency towards baser metals, as nitric and sulphuric acid have, namely, to tarnish or dissolve them, varying in quantity to differ at persons. Thousands wear continually, without any ill effect, the cheaper class of jewelry with brass ear wires, while if others wore the same article for a few days they would be troubled with sore ears, or, in other words, the acids contained in the system would so act on the brass as to produce ill results. Instances have occurred in which articles of jewelry of any grade below 18 carat have been tarnished in a few days, merely from the above-named cause. True, these instances are not very frequent; nevertheless it is as well to know them; every case is not the fault of the goods not wearing well, as it is generally called, but the result of the particular constitution by which they are worn.

Zymotic Contagion.—Prof. Tyndall asserts that diseases are propagated not by effluvia or sewer gas, but by solid particles discharged into the atmosphere by currents of air or gas. This he proved by the following experiment: He cut up a piece of steak, steeped in water, heated it at a little above the temperature of the blood, then strained off the liquid; in a short time this fluid became turbid, and when examined through a microscope was found to be swarming with living organisms; by the application of heat these were killed, and when the solution was filtered he obtained a perfectly pure liquid, which, if kept free from particles of dust, would remain pure for an unlimited period; but if a fly were to dip its leg in fluid containing living organisms and then into the pure liquid, the whole would be swarming with animalcula in 48 hours.

The Use of Nitrite of Amyl.—A few drops of nitrite of amyl have a powerful influence in restoring the functions of the heart in cases of drowning, hanging or fainting. It is suggested, therefore, that it should always be used whenever attempts are being made to restore to life an individual apparently dead, or when it is desirable to settle the question whether a person is really dead or not. Dr. Brunton says that in ascertaining death the nitrite of amyl might be used only with the test of tying a cord round the finger. If the circulation has entirely stopped, the part beyond the cord never becomes any thicker, but if the circulation continues, however slowly, the finger-tip beyond the ligature will sooner or later begin to swell.

Extracting Fragments of Metal from the Flesh.—A simple and usually successful mode of extracting a needle, or any piece of steel or iron broken off in the flesh, is accomplished by the application of a simple pocket magnet. Iron filings have a way of imbedding themselves in the eye which defies almost every ordinary means for their extraction. For their removal, a small, blunt, pointed bar of steel, well magnetized, will be found excellent, and we should recommend that workmen liable to such injuries keep such an instrument about them. It would be a good plan to insert such a bar in a penknife, in a manner similar to a blade.

Borax and Nitrate of Potash for Hoarseness.—These two salts have been employed with advantage in cases of hoarseness and aphonia occurring suddenly from the action of cold. The remedy is recommended to singers and orators whose voices suddenly become lost, but which by these means can be recovered almost instantly. A little piece of borax, the size of a pea, is to be dissolved in the mouth ten minutes before singing or speaking; the remedy provokes an abundant secretion of saliva, which moistens the mouth and throat. The local action of the horax should be aided by an equal dose of nitrate of potassium, taken in warm solution before going to bed.—*La France Medicale.*

Solvent for Salicylic Acid.—The difficult solubility of salicylic acid prevents its ready use in medicine. Kohlmann recommends acetate of ammonia as a solvent for it, and the following as the simplest plan for preparing a 20% solution for medicinal purposes: Cover 10 parts of salicylic acid with 24 parts of ammonia, shake frequently until it is dissolved, and then add 16 parts of dilute acetic acid, or just enough to produce a slightly acid reaction. The solution has a saline taste, which, however, is not at all disagreeable.

A New Surgical Conquest.—Surgery can justly boast of a new conquest; when an eye is severely wounded, the healthy one is in danger of being impaired by "sympathy;" to preserve the good eye, it was hitherto the practice to remove the injured one. Dr. Boucheron has discovered, that by cutting the ciliary nerves, the "sympathy" is stopped, and thus dispenses with the necessity of removing the injured organ. Forty surgeons have thus operated successfully,

The Week.

The convening of the Legislature this week at the State capital is an important event for California, and the members seem to have begun work in good earnest, with somewhat less of the usual bickering over positions than is usual. A bill has already been introduced with regard to reformation of certain abuses in mining stock matters, elsewhere referred to. The retiring Governor, in his message, makes the sensible suggestion that the questions between the farmers and miners, with relation to mining debris, will be better settled by discussion in the legislative halls than in the courts. In this connection we note that Congress has at last waked up, and two bills have been introduced of importance to the State. One is for the appointment of a U. S. Mining Commission of competent engineers to investigate the debris question; the other is to appropriate $500,000 towards improving the water-ways in rivers affected by the debris. All these things tend towards an early and amicable settlement of the whole dispute.

From all the mining districts we hear of hopeful anticipations, with strenuous efforts to effect their realizations. New work is being inaugurated in the leading districts, and the outlook is favorable for the approaching season.

Edison has apparently given proofs of the utility of the system of lighting by electricity, and it will be only a question of time as to when the electric light will be the illuminator in general use.

Anxiety is experienced in Europe by the warlike attitude which Russia is assuming, both in the concentration of her forces and by the extensive orders she is giving for arms and ammunition.

The influx of gold still continues into the Atlantic centers of finance from Europe, and its tendency is to greatly increase speculation and the promotion of the leading industries of the nation.

There appears among our own people to be a better state of feeling, combined with an increasing confidence, which must lead to better times.

A New Fine Ore Furnace.

Mr. H. H. Eames has put into operation at his works in Saucelito, Marin county, recently an improved furnace for smelting fine ores, such as flue dust from lead furnaces, iron sands, etc., for which he has received a United States patent, procured through the MINING AND SCIENTIFIC PRESS Patent Agency. The primary object of the invention is to feed fine ores or flue dust to the body of the furnace in such a manner as to prevent its passing up the chimney in the blast, as happens usually, more or less, in this class of furnaces. This is accomplished by turning a blast of air, previously heated by the waste heat of the furnace, into the stream of ores flowing down the feed pipe, said hot air impinging on the ore as it falls, and blowing it into the already molten mass on the hearth of the furnace. The ore is thereby prevented from clogging in the pipe, and from being carried up the chimney by the blast. A peculiar valve regulates the feed to a nicety.

The furnace devised by Mr. Eames is intended to consume crude petroleum as fuel, but any class of fuel may be used.

In the fire-bridge, between the fire-box and hearth, is a pipe or tube, and a slot is made along the lower edge of this fire-wall level with the hearth of the furnace, the slope of the hearth continuing up into said slot, so that the ore which comes into the pipe or tube on the fire-bridge is directed downward into the mass of molten metal and slag on the hearth. A tube connects with the tube or pipe in the fire-bridge and leads up to the ore hopper on top. The pipe furnishing the blast of hot air enters the tube in the bridge wall through which the ore is introduced, entering said tube just below or on line with the ore-feed pipe.

Then as the ore is fed in through the hopper and falls down the feed pipe, just as it reaches the ore-tube the blast of heated air takes it and forces it out through a slot in the fire-bridge into the mass of molten slag in the body of the furnace.

In starting up the furnace a certain amount of metal is put in through a door in the side of the furnace, and melted, so as to form a bath of metal, as it were. Then the fine ore coming in by the feed pipe is blown into the bath before it has an opportunity of being carried up the flue. The outlets for the hearth are the same as in any ordinary furnace.

One serious defect in the ordinary furnaces for treating iron sands, fine dust, etc., has been that a great proportion of the fine ore has been carried off by the blast. This difficulty Mr. Eames obviates by the method described. The fine ore does not clog in feeding, as the blast keeps it moving. The ore is heated by the blast, to a certain extent, before entering the furnace, while no heat is lost in heating the air for the blast, as it collects only waste heat, from the position of the air pipe in the furnace. This heat is again returned to the mass of the ore, being carried back by the air in the pipe.

The Debris Question in Congress.

Representative Berry has introduced a bill for the preservation and improvement of rivers and harbors in California, of which the following is the full text:

WHEREAS, The navigation of the Feather and Sacramento rivers in California is already seriously injured, and must soon be destroyed by the vast quantities of earth washed into mountain streams and their tributaries by mining operations, especially by what is known as the hydraulic process, and by precipitations of such washings by winter freshets into said rivers; and

WHEREAS, The shoaling of the waters of San Pablo and San Francisco bays and deposits around Mare Island show the rapidity with which the harbors therein are being filled and the permanent ruin that must follow; and

WHEREAS, It is the duty of the General Government to protect from injury and improve the navigable waters in the interest of commerce; and

WHEREAS, The deposits of earth aforesaid not only affect the rivers, bays and harbors of California, but have already submerged and destroyed over 100,000 acres of valuable agricultural lands, and are now jeopardizing many hundreds of thousands more, and have changed the course of the Yuba river, upon which the city of Marysville is situated, so raised the bed above the level of the streets, and have so raised the bed of the Sacramento river, upon the banks of which Sacramento city, the capital of the State, is located, as to threaten the very existence of these cities; and

WHEREAS, The State of California, in order to avert further destruction to property and to avert possible collision between the mining population and the inhabitants of the cities and valleys, has created a State Engineering Department to examine the subject and report some plan of averting further damage by deposits of mining debris in the streams of the State, by which the agricultural and mining interests can both be greatly conciliated, and cities and harbors saved from destruction; and

WHEREAS, It is for the interest of commerce that the General Government should aid in accomplishing the results sought by the State; therefore,

Be it enacted, etc., That the sum of $500,000 be and is hereby appropriated, to be expended under the direction of the War Department, in preserving the navigable streams of the State of California from injury by deposits of debris from mining operations.

The bill was referred to the Committee on Commerce.

The Solar Eclipse.

The Path of Totality—Future Total Solar Eclipses.

The annual meeting of the Academy of Sciences was held last Monday evening in the Academy building, southwest corner of California and Dupont streets. The President, Prof. George Davidson, being absent in Monterey county, locating the observatory for noting the total solar eclipse of the 11th inst., Vice-President Moore occupied the chair. Charles G. Yale, the Secretary, read the following paper on the eclipse, prepared by Prof. Davidson:

Total Solar Eclipse, January 11, 1880.

The path of the penumbra of the total eclipse of January 11, 1880, passes from west to east over the Pacific ocean, its northernmost limit being at Behring strait and its southern in the South Pacific, in latitude 27° south.

The central line of the total phase passes across the Pacific from latitude 10° north, longitude 207° west of Greenwich, through latitude 5° north and 177° west; thence northeasterly until it strikes the California coast in latitude 36° 4′, longitude 121° 35′, at 3.55·37 P. M.

When it reaches this position the sun will be only about 11 degrees of a quarter above the horizon; thence the path of the central line of totality passes across the Continent at points located as follows:

Latitude.	Longitude.	Latitude.	Longitude.
36° 09′	121° 23′	38° 03′	117° 42′
36 29	120 46	38 33	116 41
36 50	120 06	39 11	115 21
37 12	119 22	39 50	113 50
37 36	118 35	41 43	100 47

And at the last place it leaves the earth at sunset.

If the above co-ordinates are plotted on a map, it will be seen that the path of the central eclipse passes over the Salinas valley about 14 miles southeast of Soledad; over the Southern Pacific railroad near Fresno; directly over Millerton; over Eberhart, in the White Pine district; three miles south of Salt Lake City; and strikes the Central Pacific railroad at Aspen and at Bryan, near which place it leaves the earth at sunset. All the stations of the Central Pacific railroad from Webber to Bryan will be in or remarkably close to the path of totality; but of course the sun will then be in the horizon.

The width of the path of totality will be little over 30 miles, and the duration of totality about 35 seconds.

The time of totality where it crosses the Southern Pacific railroad will be nearly 40 seconds later than when it strikes the coast, and the sun will be about 10 degrees high; and under ordinary circumstances of atmospheric disturbance from irregular refraction the limbs of the sun and of the moon will not be sharp and steady. It is most likely that both bodies will exhibit "spurious disks," and the limbs of both be blurred and confused. Under such circumstances the phenomenon of "Baily's Beads" will be exhibited just as the last line of the sun's edge disappears behind the moon. This bright line will then be broken into a wavy line of bright spots. The phenomenon will recur upon the re-appearance of the sun's bright limb. Should the atmosphere be remarkably steady, then this phenomenon will not be present, but the fine line of the sun's disappearing edge will be continuous and *disappear as a line;* it will *also re-appear as a line* at the third contact.

The report of the eclipse of 1869, as observed in Alaska, fully established the last named condition; and then, as on previous occasions, it was shown to the California Academy that the phenomenon of Baily's Beads, the "black drop" in transits of Mercury and Venus, and similar phenomena, were the results of atmospheric disturbances. This view has been strongly controverted, but now leading astronomers are satisfied of its soundness. No other explanation, such as the diffraction of light, the existence of lunar mountains, peculiarities of the telescope, etc., explain all the phenomena observed, and especially fail to account for the phenomenon exhibited when the Baily Beads, etc., are not present.

It is to avoid this atmospheric disturbance that the Coast Survey party has chosen to reach the more difficult station on the path of totality in the Santa Lucia mountains, about 35 miles southeastwardly of Point Pinos, and Prof. Frisby of the U. S. Naval Observatory has also determined to occupy the same locality with his instrument.

Of course, where the whole available time of totality is only about half a minute, it is a miracle if any other work is done than obtaining the epochs of the first three contacts. Yet the Coast Survey party is prepared to determine the position of any intra-Mercurial planet, should one fortunately be discovered. It is safe to say that there are a million of chances to one against catching such an object, and yet the millionth chance may be the first one that turns up. There will be five instruments and five pairs of eyes accustomed to observing; the station will probably be over 5,000 feet above the sea. If the day is propitious, the observers may expect an atmosphere so steady that stars of the fourth and perhaps of the four-and-a-half magnitude will be visible to the naked eye. It happens that no star of the fourth magnitude lies within 10° of the sun; but to familiarize the observers with the heavens in the vicinity of the sun, a map has been prepared, to embrace 16° on each side of the sun, in the line of the elliptic, and 8° above and below this line. This chart exhibits stars down to the seventh magnitude, although it is doubtful if stars of less than the fifth magnitude can be seen by the sharpest eyes or even with an opera glass. Nevertheless they would be visible in the telescopes and might prove serviceable objects for comparison.

The letters of Peters, Watson and Swift in the *Astronomische Nachrichten*, upon the subject of the Vulcanites supposed to have been seen by the two latter observers, indicate the great doubt which exists upon the subject of the intra-Mercurial planets, a doubt which is shared largely in Europe. Whilst the observations of such experienced men as Watson and Swift may not be doubted under all ordinary circumstances, yet under the extraordinary conditions attending their measures in July, 1878, a reasonable doubt may fairly be entertained as to whether they saw two new inferior planets or two stars. And this subject must remain obscure until observations are secured admitting of no doubt.

According to Hind we may reasonably expect to increase our knowledge of the physics of the sun, and of the existence of vulcanites at the following important total eclipses among others, which occur in the next twenty years:

Date. Year.	Date. Month.	Most Favorable Locality for Observation.	Duration of Totality.
1882	May 17.....	Arabia.....	2′ 00″
1883	May 6.....	Marquesas Islands.....	5′ 15″
1885	Sept. 9.....	New Zealand.....	2′ 00″
1886	Aug. 29.....	West Africa.....	6′ 21″
1887	Aug. 19.....	Russia.....	3′ 49″
1889	Dec. 22.....	Angola, West Africa.....	3′ 34″
1893	April 16.....	Brazil.....	4′ 44″

It will be noticed that the length of totality in several of these eclipses is remarkably prolonged, affording unusual opportunity for systematic, calm and deliberate observation.

In the meantime we may expect that new instrumental means and methods will be devised for the solution of questions of solar physics yet in doubt; and it is not beyond the bounds of probability that the instrumental means may be utilized even without eclipses, as has been the case in the spectroscopic observations upon the sun flames at any time.

Recent eclipses have set at rest the question of the corona being a solar appendage not self-luminous, but shining by reflected sunlight; and yet much remains to be done, and even new questions arise as older ones are explained and satisfied.

The next total solar eclipse visible near the United States will be that of May 28, 1900, at 3 o'clock in the afternoon; wherein the central line of totality passes through Mexico, the Azores and Egypt.

In the latitude of San Francisco the eclipse on the 11th instant will not be total, but eleven and four-tenths digits, or ninety-five hundredths of the sun's diameter will be obscured, so that decrease of light will be very sensibly felt.

The first contact will occur at a point on the sun's limb 30° to the right from the lowest point of the disk, 2h. 42m. 3s., mean time for San Francisco.

The disk of the moon will rise nearly vertically over the disk of the sun, and at the latitude of San Francisco above the sea, the sun will set with the moon's lower limb still four minutes upon the sun's upper limb. Were an observer at a great elevation above the sea, he would see the moon leaving the sun at a point twenty degrees to the left of the highest point of the sun's disk.

The time of greatest obscuration will be about three hours and forty-nine minutes, when a bright, narrow segment of the sun will be visible on the right side.

To most persons it will be a novel sight to witness the progress of the eclipse as the sun approaches the horizon, and finally to see the sun set with the small segment of the moon's disk yet upon it.

SUSPENSION AND ELEVATION OF CLOUDS.—M. Oltramare supposes that the altitude of clouds is determined by the force of electrical repulsion between the clouds and the stratum of air below them. If the electricity is uniformly distributed, in accordance with any simple function of the height, the hollow sphere of air above the clouds can exert no influence.

A TERRIBLE story is told of the sufferings and outrages endured by the women of the White River Agency while captives of the Indians.

DURING 1879 the product of precious metals west of the Missouri river, including British Columbia, was $5,805,121 less than in 1878.

SEARCH for the victims of the Tay bridge disaster in Scotland has been suspended, on account of the boisterous weather.

THREE men were killed and two others fatally injured at Newark, N. J., by an explosion in a celluloid manufactory on Monday.

THE shipments of treasure from Portland, Or., by Wells, Fargo & Co. during 1879 amounted to $3,554,507.

GOV. CORNELL was inaugurated Jan. 1st at Albany, N. Y., in the presence of a vast concourse of citizens.

The Tay Bridge.

Details of Construction of the Longest Iron Bridge in the World.

The terrible accident which occurred at the Tay bridge, in Scotland, recently, and the fearful loss of life on that occasion, has called the attention of the civilized world to the danger and liability of accident from lack of strength in bridges; and civil engineers everywhere will have a fruitful source for discussion for some time to come. The traveling public will look to the engineering profession to correct in future structures the defects which must have existed in the one so lately destroyed, which will necessitate a most careful and searching investigation into every detail of construction. The exigencies of our modern systems of land transportation, in which the railroad is the great factor, have necessitated the building of bridges of more magnitude of proportion than formerly, in order to open communication with fresh centers of industry, and afford facilities not only for passengers, but those commodities which contribute alike to national and individual wealth and comfort.

It is to that noble band of workers who, with wise head and busy hand, are doing what they can to promote the progress of physical science and to extend the dominion of man over the power of nature, that we look to insure us against accident on structures of this character. They set themselves to grapple with and to overcome difficulties of no ordinary kind—physical difficulties which, to the common mind, seem insuperable; and yet success has crowned their efforts in so many cases that this one failure, so marked in its results, will meet with closer scrutiny and attention from every individual in the profession than would any proposed principles, schemes or plans, of whatever magnitude.

Iron Bridges.

Although we are told by Du Halde that iron bridges originated and were first used in China, the first of which we have authentic record was an arch of cast-iron spans erected over the Severn at Coalbrookdale, Shropshire, England, by Abraham Darby and John Wilkinson, in 1779. When increasing trade required greater facility for carrying passengers and freight, the arch was found inadequate to carry a roadway over an arm of the sea or a broad and swiftly flowing river. Accordingly the idea of suspension bridges was carried out, numbers of which are to be found all over the world. It was soon found, however, that the legitimate use of suspension bridges was the carrying of ordinary roads over large spans where the loads were not so great nor motion so swift as on railways; and although many of them are used for railways, more solid structures are preferred where practicable. In searching for some other form of roadway, when the younger Stephenson was employed to carry the Chester and Holyhead railway across the Menai strait, he proposed to effect his purpose with a circular tube supported by chains. It is said by some, however, that the idea of this wrought-iron tubular bridge and the carrying out of the details of construction which made it a success are due to Fairbairn's, to whom the credit is due of devising the form and proportions of the tubular bridges of Menai and Conway. The rectangular cellular beam laid on its edge and made of wrought and cast iron in their respective places, was Fairbairn, as was also the idea of making it self-supporting. Stephenson gave up, very reluctantly, the idea of supporting it by chains. A similar principle, that of the truss beam, has been applied, varying of course in details of construction, all over the world. The success of the Britannia and Conway bridges led to the construction of many similar, such as the Victoria bridge over the St. Lawrence, etc.

Successful as these bridges were, the waste of material was too great to allow engineers to rest on the idea that nothing more required to be done, and it was ultimately found that the lattice girder, such as was adopted on the Tay bridge, would be as strong, and by presenting less surface to a gale of wind, as secure.

Difficulties to be Overcome at the Tay.

The most notable difficulties in connection with the construction of the Tay bridge were caused by the boisterous character of the weather in the river, and the nature of its bottom. Each of these circumstances by itself would have rendered the use of ordinary scaffolding and staging impracticable. Had this not been the case, the cylinders might have been built, lowered and steadied from a reliable staging, and the girders, during their erection, rested on secure scaffolding till they were finally connected to the piers. Everything would thus have been plain and straightforward, and the bridge would only have differed from a thousand similar structures all over the world by the fact that it is the longest of them all. As it was, however, new methods of construction had to be invented and tried, sometimes at considerable expenditure of time and money. It is, of course, necessary to introduce modifications to suit different circumstances. In the methods employed at the Tay bridge, there were many which had never before been used, and these possess a high interest for the professional engineer and the general public, especially in view of the disastrous results. The work was much more difficult to perform than was anticipated, as the nature of the river bottom turned out to be quite different from what the official borings had given reason to expect. The plans for foundations and piers had to be materially altered. Contracts for ironwork had to be undone, and new ones entered into, and a "plant" had to be made to suit the altered method of working, after a good deal of work had already been done.

Inception of the Idea.

It is to Mr. Thomas Bouch, when engineer and traffic manager of the Edinburgh, Perth and Dundee R. R. Co. that the bold design of bridging not only the estuary of the Tay but also that of the Forth is due. In his official capacity he had frequently been a witness of the inconvenience and danger of the ferries at Tayport and Burntisland, and a fatal accident at the latter place in 1849 quickened his perception of the costliness and clumsiness of that system. It was not, however, until 1854 that he proposed the scheme to the directors of the Scottish Northeastern R. R.; but he was looked upon as a dreamer, and it was not until 1863 that a public proposal of the subject was evoked, when the first public expression of a belief that the "Storm Fiend of the Tay" might be met and defied in his own domain was made in the Dundee *Advertiser*.

History of the Undertaking.

The local and Parliamentary history of the Tay bridge bears too much resemblance to that of all great schemes of improvement, and the narrative is full of conflicts, struggles, obstructions and hindrances. From the time in 1864 when Parliamentary notice of a bill to provide for the incorporation of a company to build the bridge, until the time the work was started in 1871, there was a continual fight between railroad companies, promoters, Parliamentary committees, town councils, harbor boards, etc. Four or five plans were adopted, drawn up in detail, and then changed. Numbers of people were possessed of grave doubts as to the *bona fide* nature of the scheme, and looked upon it as a strategical manœuvre of the North British R. R. Co. to bring opposing interests into their designs elsewhere. The town council of Dundee, while they did not object to the bridge, wanted a footway for passengers; the trains arranged to suit the convenience of the public; and the fixing of a specified rate of fare within reach of the whole community. To prevent an undue use of proprietorial rights, they wanted more than one company to have an interest in the bridge; and they insisted on a double track. The Dundee Harbor Trust also entered into active opposition; and the Perth Town Council, in the interest of their decaying shipping trade and port, put in a claim to be heard against the contemplated obstruction of the river. It was to the latter influence that concessions were made necessitating the hight of the bridge above tide water and the width of span with which the bridge was built.

It was during this fight that the question of the right of Scotch municipalities to defend the interests common to all was denied. It was decided, however, that they had, a most important victory for the governing bodies of the Royal Burghs of Scotland. If they had submitted to the decision which deprived them of all power to interfere on behalf of the communities they represented, such submission would have formed a precedent quotable against them in future emergencies of a like nature, and railway companies would have used their new-found powers without consideration of other interests than their own. After difficulties were all settled, rights to shore line granted, certain acres sold for stations, etc., opponents came, within the North British R. R. Co. itself.

The Disaster Predicted.

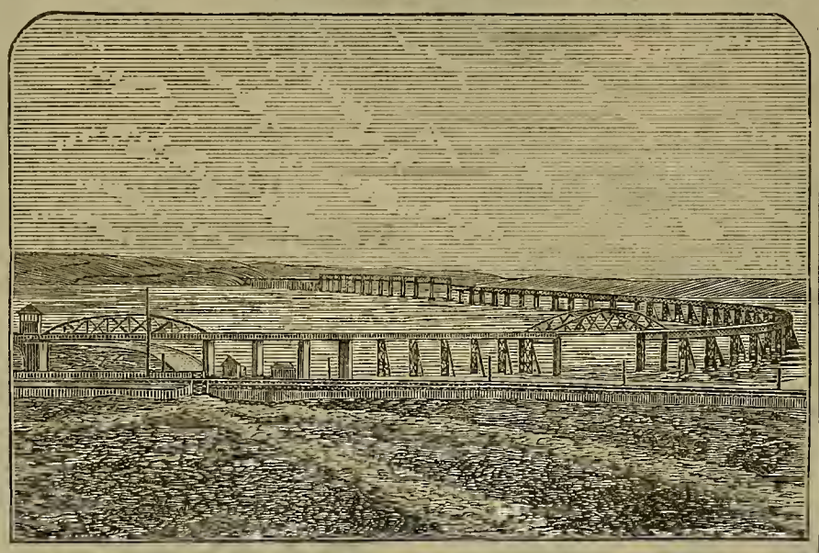
Then Mr. Patrick Matheu, in a series of letters to the Dundee *Advertiser*, endeavored to shake faith in the scheme. He did not think they could build this "high slender rainbow-like structure strong enough to protect it from the fury of the waves or the destroying breath proceeding from the storm throat of the Tay." He thought that "deep channels would be scooped out by the increasing current around the piers," and that the foundations would be undermined; or that vessels dragging their anchors might destroy a pier. Among other things he wrote: "Yet a little while and a train filled with happy people is swiftly proceeding along the tortuous structure. Its weight and velocity act with such a centrifugal force upon the curve that the workmanship is unable to bear the strain; the bridge opens up and the train with its human freight is precipitated into the river a hundred feet below. An islet is now seen in the Firth where no islet existed before, and its component parts are stones, fragments of iron and of wood, together with mangled human bodies, and the eels are gliding in and out between the interstices of the horrible scene. The bridge itself is a wreck, never more to be used as a means of communication between the counties of Fife and Forfar."

This gentleman died before the bridge was completed, and his assertions were so ridiculed at the time that they earned for him the soubriquet of "The Seer of Gourdie Hill." His prophecy came true, however, by whatever means the catastrophe was brought about.

What had to be Done.

There is little doubt that the railway company would willingly have made the bridge to carry double tracks, but the tardiness with which the stock was taken up made it incumbent on them to provide for nearly a third of the capital required. They were, therefore, compelled to content themselves with the single track, and to rely upon its success as a single track line to induce the public to provide additional capital to double the means of transit.

The bill allowing the arrangements to be carried out passed the House of Lords in July, 1870, and in a few weeks received the Royal assent. Details then had to be considered of the great work.



THE IRON BRIDGE ACROSS THE FRITH OF TAY.

It was the erection of a railway bridge over the widest tidal river that had ever been spanned—a river with a deep rapid current, and subject at all seasons to violent gales which sweep down the estuary, as through a funnel, with the concentrated force of a tempest. On all hands the difficulties were admitted to be very great, while not a few regarded them as perfectly insurmountable, boldly asserting that in a trial of strength it would be found that engineering skill would be unable to cope with the forces of Nature. But the construction of the high level pontage, in itself to be regarded as a signal trumpt of science, was an undertaking of paramount importance to the North British R. R. Co., not only because it would more effectually open up the collieries of Fife and shorten the distance between Edinburgh and the North, besides saving the cost of ferry and tollage (about £13,000 per annum), but more particularly because its erection was the initial step towards the far greater object in view—the bridging of the Forth; and accordingly the scheme was entered upon with resolute determination, which was an omen of success.

The Engineers.

To Mr. Thomas Bouch, the North British Railway Company's eminent engineer, the originator of the scheme, the plan of the Tay bridge is due. The *modus operandi* for its construction was left to the contractors, Messrs. De Bergue & Co., and afterwards Messrs. Hopkins, Gilkes & Co. The managers for these contractors were Albert Grothe, Edward R. Austin and Mr. Edgar Gilkes. The Railway Company's resident engineer was Mr. Wm. Paterson. An enthusiastic staff of young engineers were also enlisted, of whom Mr. Reeves invented the sand pump, which did so much to facilitate the work; Mr. Frank Beattie devised the appliances for lifting the 245 feet spans to their resting places 88 feet above high water, and Messrs. Delprat, G. W. Camphius and T. C. de Bruyn.

Length of Spans.

As a melancholy interest attaches itself at the present time to this famous bridge, a brief general description will enable the reader to understand more readily what few details of the process of its construction we propose to give; and the engraving shown herewith gives a general view of the completed structure.

Starting from the Forth end the bridge crosses the river almost due north and south for about three-fourths of the distance, when it makes a curve, having a radius of 20 chains, to join the land line which runs at right angles. The bridge is 3,450 yards in length, and consists of 85 spans of the following dimensions:

11	spans	of	245	feet	each,	lattice girders.

Construction of the Piers.

In the case of the two spans of 227 feet and the 11 of 245 feet, and on the bowstring span, the roadway is carried on the bottom booms of the girders, while on the other spans it is laid along the tops of the girders, this arrangement, in the case of the wide spans in the center of the river, allowing a clear water way for the passage of vessels to and from Newburgh and Perth. The piers are of varied construction, but in most cases the foundations are formed of iron cylinders filled in with brick and concrete. Piers 1 to 14 are entirely of brick in cement. Piers 15 to 48 are brick for five feet above high water, finished with a stone belting, upon which are carried groups of cast-iron columns braced together. Piers 49 to 77 consist of groups of cast-iron columns braced together, starting from the cylinders and encased in brickwork to a hight of five feet above high water. Piers 78 and 79 are cast-iron cylinders throughout, filled with concrete. Piers 80 to 84 are cast-iron columns. In form the bridge is slightly arched, the greatest hight being at center of large spans—88 feet. The gradient is 1 in 365.

The chief difficulties were connected with the formation of the piers under water. In previous years the only plan of constructing such piers was by forming a coffer dam and then pumping out the water and building from the foundation; had no other mode been available, this bridge would never have been built on account of the expense.

Floating out the Piers.

The piers and girders were built on shore and floated out to their destinations, so as to dispense with heavy staging and scaffolding. A place on the beach was leveled and a concrete floor laid. The first plan adopted was to build and sink separately the two cylinders composing each pier. Each cylinder was laid on the concrete floor, filled with a lining of brick-work up to low water level, leaving an opening at the center. This then, weighing 40 tons, was floated out on pontoons and sunk. The water was forced out by air, men went in, and as they dug the pillar settled till rock was reached. Concrete was then put in. Trouble was experienced from the narrowness of the base of the cylinders, as they would very frequently list over; so they discontinued the practice of sinking the cylinders singly. To overcome this difficulty it was resolved to make each pier, not of two separate pillars, but as a complete structure, consisting of two engaged cylindrical pillars rising from a common base, having long straight sides and circular ends. This plan was very satisfactory. For the construction of one of these combined piers there was provided, first of all, a wrought-iron base 3 feet high, 22½ feet long and 10½ feet wide, with flat sides and circular ends, which was laid on the temporary concrete floor on the beach. This base was surmounted by a conical cast-iron cap 4 feet long, furnished with a top flange 2½ feet wide; the base and sur-base making a hollow chamber 8 feet high, and big enough for two gangs of six men each to work in. On the broad flange of the sur-base brickwork was carried up to the level of low water in two circular towers, 9½ feet in diameter, surrounded by cast-iron cylinders of ⅜-inch metal in four segments; a shaft 4 feet in diameter being left in each tower for the descent of the workmen to the chamber at the bottom. To transport this very

Unwieldly Mass of Brickwork

Of about 140 tons in weight from its temporary resting place ashore to its permanent position in the bed of the river, a simple but ingenious arrangement was introduced by Mr. Austin.

Two pontoons, each bearing two strong malleable iron girders, besides hydraulic rams to lift 60 tons each, were floated, so as to bring the pier into the center between the girders. The latter were connected by wrought-iron links with the base of the pier, which was provided with vertical suspending links. To these were connected a pair of balancing cross head plates, while the upper and lower sets were attached to the wrought-iron links. The hydraulic rams had a stroke of 12 inches, and the links,

Hidden Treasure Mining Company.

Through the courtesy of the officers and members of the company we have received through M. H. Power, Secretary, the annual statement of account of the Hidden Treasure mining company, located at Sunny South, six miles above Michigan Bluff, in this county. From the day gravel was first struck in this claim, which was about May, 1876, the mine has proved a success, and consequently we have at various times had occasion to revert to its operations. Never before, however, have we been able to give exact figures, data which is always gratifying to the publisher, and particularly so to the inquiring public. The statement for the year commencing Jan. 1, 1879, and ending Dec. 20, 1879, is as follows:

RECEIPTS:

Jan. 1, 1879, cash on hand	$112.25
December 20, cash received for sale of gold dust during the year	98,437.15
Cash received from sundries	236.89
Total receipts	$93,786.29

CONTRA:

By cash paid for wages	$36,530.34
By cash paid for other purposes	7,967.60
By cash disbursed in dividends	53,280.00
By balance on hand	8.35
Total	$97,786.29

This showing we consider a peculiarly gratifying one. A mine that distributes $37,530.34 in wages each year is a good thing for the country, though it should do little else. When, however, a mine, after distributing this large sum as wages, distributes the much larger sum of $53,280 among its stockholders as dividends, it certainly is a very desirable property for the country in general and the stockholders in particular. Few mines in the State, we believe, according to its capacity, can make a better showing. Another gratifying feature connected with the marked success of this mine, is the fact that its owners are nearly or quite all practical miners and withal an exceptionally fine lot of steady, sober, industrious and intelligent gentlemen. Still another encouraging feature is the fact that it is a mine that promises to last for many years.—*Placer Herald.*

BOWER'S RUST PREVENTIVE.—Carbonic acid, generated by the combustion of carbonic oxide, is allowed to act upon iron or steel at a moderately high temperature; or, a layer of sesquioxide is first produced, and a mixture of carbonic acid and air is afterwards passed over the red-hot metal.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions free from all technicalities, and in such a style as to be easily comprehended. It is written for the minor, with no hemical symbols or metallurgical technicalities to confuse hose who are not chemists or metallurgists. The follow ng summary of the contents of the work will give an dea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working same ple, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Krochnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks; dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, $2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

TO APPEAR SHORTLY.

Grimshaw on Saws.

History, Development and Action, Classification and Comparison, Manufacture, Care, and Use of Saws of all kinds. 8vo. Illustrated. By ROBERT GRIMSHAW.

This thorough little work, impartially written in a clear, simple and practical style, and supplemented by valuable tables, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small Hand, Sash, Mulay, Jig, Drag, Circular, Cylinder and Band Saws, as now and formerly used for cross-cutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With Appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc.; tables of gauges and other valuable information. Elegantly printed on extra heavy paper. Subscription price, $1.50. Orders for first edition received now.

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city:

Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Huerne, John Marquis, B. McDougal & Son, Wm. Mooser, Wm. Curlett, Meeker & Banks, W. C. Hoagland, S. & J. Newsom, B. Henrickson.

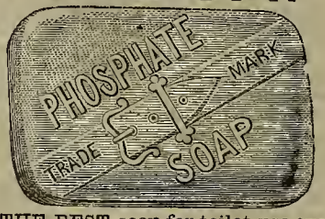
PHOSPHATE SOAP



THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detersive qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If you wish to make your hands soft buy a cake of PHOSPHATE SOAP, and when that is gone you will buy a dozen and recommend your friends to do the same.

Ladies who wish to make the skin look beautiful and natural should use PHOSPHATE SOAP.

For chapped hands the constant use of PHOSPHATE SOAP will be recommended by all who give it one fair trial.

TESTIMONIALS.

SAN JOSE, September 24, 1879.

To the Standard Soap Co.—Gentlemen:

It affords me pleasure to say to the public that I have used and prescribed your PHOSPHATE SOAP as a remedy in various forms of cutaneous diseases with the happiest results. I am of the opinion that it is the mildest and most perfect detergent that can be used, either for cleansing the skin and leaving it soft and healthy, or for removing the fetor and corroding influences of sores and ulcerations. I should be sorry to be without it in shaving my face or making my toilet, to say nothing of my good opinion of its remedial qualities.

A. J. SPENCER, M. D.
SAN FRANCISCO, Aug. 27, 1879.

Gentlemen:

I received a package of your soap (Phosphate Soap) and it gives me great pleasure to testify as to its superior excellence. As a toilet soap I have never seen anything to surpass it. It also possesses superior remedial qualities. I have used it in two cases of obstinate skin disease, one of intolerable itching, *Pruritus*, the other an *Eczema*. In both great relief was obtained. Its emollient properties are remarkable. Respectfully,

W. A. DOUGLASS, M. D.,
126 O'Farrell St.

To the Standard Soap Company.

SAN FRANCISCO, July 19, 1879.

Standard Soap Co.—Gents:

I have tried your PHOSPHATE SOAP, and have no hesitation in saying that it is the best toilet soap I ever used. My wife has used it and is of the same opinion. I have paid as high as fifty cents per cake for an article in every respect inferior to what you sell for twenty-five cents. HENRY H. LYNCH,
515 Haight street.

The genuine merits of PHOSPHATE SOAP and persistent advertising will force every druggist, groceryman and general dealer to order it by the gross sooner or later. Ask for it in every store. The retail price is 25 cents per cake. We wish to sell it only at wholesale, but in case you cannot find it we will send a nice box of three cakes by mail, postage paid, on receipt of 85 cents in stamps.

Ingersoll Rock Drills.

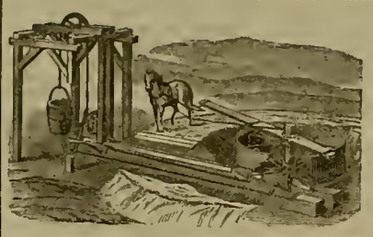
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.

The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

NO. 413 MONTGOMERY STREET,

San Francisco, Cal.

Diamond Drill Co.

The undersigned, owners of LESCHOT'S PATENT for DIAMOND POINTED DRILLS, now brought to the highest state of perfection, are prepared to fill orders for the IMPROVED PROSPECTING AND TUNNELING DRILLS, with or without power, at short notice, and at reduced prices. Abundant testimony furnished of the great economy and successful working of numerous machines in operation in the quartz and gravel mines on this coast. Circulars forwarded, and full information given upon application.

A. J. SEVERANCE & CO.

Office, No. 320 Sansome street, Room 10.

CONTINUED FROM PAGE 21.

depth is of better quality than anything yet taken out. The tunnel is being worked from both sides of the hill, and the width, 750 ft, will soon be tunneled.

NEW DISTRICT.—The Siegle district, Sierrita mountains, about 30 miles southwest from Tucson, is attracting considerable attention. A. H. Soles is in this week and has received highly satisfactory assays from ores brought from his mines. On his last trip he took up the 1814 mine, so called from its apparent antiquity. He finds an old tunnel which he entered to a depth of 110 ft, and was obliged to return, his light going out. The tunnel shows a good vein of ore with clearly-defined walls. There seems to be in this immediate vicinity many such veins.

MODEL MINE.—*Miner*, Dec 26: The Model mine, in Peeples' valley, has paid its way for several months, and left a large dividend for its owners.

PLACER GOLD.—Mr. C. C. Bean informs us that during the summer and fall just passed a number of Mexicans have been working the placer claims on Arastra creek, between Walnut Grove and Peeples' valley, and that they have weighed their earnings on the scales of an American living in that vicinity, amounting to over $10,000. This is a new quarter which has been producing gold in paying quantities.

REDUCTION WORKS.—George M. Pinkham, of Oakland, Cal., arrived in Prescott this morning and informed us that he has purchased a complete quartz mill for his mines in Mohave county, which has just been shipped from the foundry of Scott, Prescott & Co., San Francisco, weighing 240,000 pounds. The mill will be one of the most complete ever put up in the Territory. We understand there is in the treasury sufficient funds to pay for everything and much more, therefore we expect to see the grandest reductiou works in Mohave county ever put up in Arizona.

COLORADO.

VIRGINIUS.—*Register-Call*, Dec. 26: Prof. R. W. Woodward, Vice-President of the Windham smelter, San Juan, Ouray county, states that he has milled 80 tons of ore from the Virginius silver mine, which ran as follows: First class, 781 ounces per ton; second, 395 ounces; third, 225 ounces. There was only one ton of third class. The Virginius is one mile from the Snuggler, on the same mountain.

CALIFORNIA.—The mill ore from the 1000 level in the California mine, on Quartz hill, is running nine ounces gold per cord.

IRENE.—Capt. John H. Bowen will commence developing the Irene lode, in Quartz Valley district. The main shaft is to be carried down to a further depth of 100 ft.

KINGSTON.—Two drifts are being run west in the main shaft of the Kingston vein, property of the Illinois mining and milling company, of Chicago, which vein is in Russell district.

PYRENNES.—The recent lessees of the Pyrennes lode, west of the Nimrod, in Russell district, have commenced to work the mine.

CYCLOPS.—The last lots of ore sold from the Wilson & Cross shaft on the Cyclops vein, Silver mountain, gave a return of 250 ounces per ton for the first class and 85 per ton for the second class, over and above treatment.

WHITNEY.—The contractors for sinking the last lift in the Whitney main shaft, in Eureka mining district, are driving work.

HARKAWAY.—It is quite probable that the Harkaway mining and milling company will resume work in the main shaft of the Harkaway mine shortly. The new 10-stamp mill and other machinery has all been received.

PEWABIC.—A large-sized pump will be put into the Pewabic mine, in Russell district. It is being removed from Blackhawk and will be in position soon.

COMMONWEALTH.—*Miner*, Dec. 27: This mine is owned by J. B Johnson, and is located in East Argentine district. Joe is running in an adit on the lode, which is now about 200 ft in length and carries five inches of ore of fair grade.

ANDREWS LODE.—This mine is located near the Main Range, and is owned by a Boston company, which is developing the property.

SHIVELY.—Has erected mining machinery and made permanent improvements. During the past six months a tramway 1,500 ft in length has been constructed from the gulch to the mine. An engine has been erected on the dump for operating the tramway, and a large hoisting engine has been placed in the subterranean chamber on the Fletcher tunnel, blasted out for that purpose, and a couple of Ingersoll drills and a Clayton air-compressor are to be added soon. The Shively has invariably carried high-grade ore composed of sulphurets and argentiferous galena, and fine specimens of ruby silver have frequently been found. The sinking of the engine shaft and the drifting ahead of the Fletcher tunnel will be the principal feature of development henceforth. The Shively is one of our best mining properties.

IDAHO.

OWYHEE.—Butte Mountain *Miner*, Dec. 23: A recent crushing of 120 tons of rock from the Owyhee mine, yielded over $21,000. This mine continues to hold its own in the way of contributing to the bullion shipments of this section of the country.

YANKEE FORK.—*Herald*, Jan. 3: The Hope is looking well. The tunnel being driven on the vein will be continued a distance of 100 ft, which will give it a depth of 75 ft from the surface. We were in error last week in stating that the tunnel was being run to tap the vein. It was started directly on it and will so continue.

MINE TAPPED.—*Idaho World*, Dec. 27: Mr. Hugo Bayhouse was over from Centerville two or three days ago. He informs us that he and J. L. Jackson, who relocated the quartz mine about a mile this side of Centerville, a short time ago, have tapped the mine with a tunnel and found a good body of ore. It will average about $30 per ton. The owners of the mine are putting the tunnel in shape, preparatory to stoping.

MONTANA.

RICH STRIKE.—*Northwest:* A rich quartz strike is reported from the district at the head of First Chance. Henry Grant is the owner of the lead. A shaft was sunk last winter, but no quartz of any value was discovered, and the vein was lost. A tunnel was started in to strike the shaft, and in running it the vein of gold-bearing quartz, said to be the richest by far in Montana was discovered. There is considerable excitement over the find in and around Bear. There are many locations in the immediate vicinity of Mr. Grant's lode.

DISPATCH.—Butte Mountain *Miner*, Dec. 23: This mine, owned by Farlin Bros., lies directly east of the Dexter mill. Three shafts have been sunk on this claim. Ore was extracted which worked 102 ounces. The west drift from the bottom is in 30 ft, and shows two ft of ore. Ore has been extracted from shaft No. 3 which worked 125 ounces.

ALICE MINE.—The contractors have resumed work on the 500 level, and are pushing the drifts east and west as fast as possible. They are opening up a great deal of exceedingly rich ore. On the 400 level the breast of ore now opened is nearly 50 ft in width, some of which is of high grade. They are extracting about 25 tons of first-class and 15 of second-class ore daily.

WESTERN WORLD.—This mine, owned by Messrs. Owsley, Allport, Ransom & Frank, is situated directly west of the Andy Johnson. Two shafts have been sunk to water level. A lot of ore was extracted in this portion of the mine which assayed 45 ounces in silver and $7 in gold.

MORNING STAR.—The new shaft on the east end of the mine is down about 20 ft. It is sunk south of the croppings. The bottom of shaft No. 2 shows a streak of high-grade free ore 22 inches in width. From the west drift, 50 level, considerable high-grade free ore is being extracted.

ANCIENT.—This mine, situated on the Black Chief lode, is owned by W. A. and Jos. K. Clark. A tunnel was run north 200 ft near the surface and showed a ledge formation from 50 to 60 ft wide. Three shafts have been sunk on different spurs, the deepest of which is now down about 40 ft; from this shaft considerable ore has been extracted, which worked in the Dexter mill from 30 to 50 ounces.

The Tay Bridge.

CONTINUED FROM PAGE 25.

passed through slotted holes in their hases, were perforated with holss corresponding to stroke of rams. Being fixed to the piers at low water, the girders gradually,lifted as the rising tide raised the pontoons, and the whole mass was suhsequently towed out at high water, the weight of the pier, which was suhmerged 8 feet, being carried on steel pins. When the pontoons had been securely anchored, the lowering process hegan. To lower the pier, the cross-heads on the rams were connected hy pins with the links at the top of the stroke. Then

The Hydraulic Force Pump,

Of which there was one on each pontoon, with a few strokes raised the pier ahout an eighth of au inch, so the weight was no longer on the steel pins, which were then drawn out and placed in the link holes a foot further up. By means of cocks the water was let out of the rams, first on one side and then on the other, and the pier lowered until ths steel pins again rested on their hearings. The cross-heads wsre then disconnected, and the rams pumped up again to the top of the stroke. As ths lowering proceeded, liuks, four feet long, were added, and the whole apparatus, although weighing ahout 140 tons, was under perfect control. It was lowercd about one foot in five minutes, so by full ehb it was grounded on the river hed. During its settlement in the silt the pier was carefully watched by a spirit level, and any tendency to sink unsvenly was checked hy the hydraulic rams heing pumped up on the lower side.

When once the pier was settled in its proper site, temporary cast and wrought-iron caissons were fixed upon it, so as to briog it ahout six feet ahove bigh water, and brickwork was then carried up until weight enough was added to prevent the pier floating when filled with air during the process of sinking it in rock foundation. This operation was effected by

Two Air Bells,

With pumpe and engines attached, which were fixed to the top of the caissons. Air was pumped down the shafts of the piers until the water was driven out of the chamber at the hottom, to which the workmen then descended in diving dress and excavated tbe soil. The sand and gravel were sent up in huckets through lock-shoots in the air-hells. As the pier sank by its weight, two hydraulic telescopic legs steadied it. On reaching rock the foundation was levcled. The working chamher was then filled with concrete, under air pressure, the flanges carrying tbe hrickwork being carefully packed and run in with cement concrete. The shafts were next filled up, tbe air-bells and temporary caissons removed, and brickwork carried up to the requisite hight.

Difficulties With the Foundations

Were greater than anticipated. The rock hed suddenly dipped to a depth practically inaccessible, which led to a complete change in procedure. The original plan contemplated the erection of solid brick piers for supporting the girders over the greater part of the river, it being understood rock formation would be found. The contractors had, however, not only to form an artificial rock foundation, but also to lessen the *top* weigbt. The latter object was gained by suhstituting groups of iron columns in lieu of brick, ahove high water, while an artificial rock foundation was made hy forming oval beds of concrete, laying them on the clay or gravel. In some places, piles 40 feet long were driven in before these concrete beds could he laid. Caissons were used in forming these heds, but sinking them was troublesome. At last Mr. Reeves devised

A Sand Pump.

He placed four receivers of upright iron in a small lighter with necessary engines and air-pumps, tuhes leading from said receivers down into the caisson. By exhausting the air ahove, and having divers holding the ends of the pipes helow, the silt and water rnshed up into the receivers. As the soil was removed from the interior the caisson gradually sank, and at a depth of 18 or 19 feet, clay or gravel was generally reached. Ahout two and a half minutes served to fill a receiver, sand forming one-third of its contents, and, as dnring this time the engine was exhausting one of the other receivers, the work was continuous. About 100 tons of material a day were thus raised. A machine on a similar principle tried in our California river heds for gold mining, was not successful, no euch amount heing raised.

The Caissons.

The caissons were then packed with concrete, and a mound of ruhble raised around the hase to protect it from scour of the river, and the result was the formation of a solid foundation, capable of sustaining the immense weight of the superstructure. When the temporary caisson was removed, the coucrete foundation projected ahout a foot above the river bed, ready for reception of the pier. The lower portion of the pier, permanently under water, was bnilt of cemcnt and brick *on shore*, with tbe center hollow. Being 22 feet deep, the brickwork, when securely fixed on its foundation, had its top level with the surface at ebb tide, and the men then filled in the cavity with concrete, and huilt up 14 feet of solid hrickwork more, to high water. Four courses of stone, five feet thick, were then put in, to form a base for upper worke. These consisted of eix iron columns, 12x15inches, cast in 10 feet lengths, and securely holted together and made fast to each othsr hy hraces. Fourteen piers of this style hrought the works to the middle of ths river.

The Central Spans where the Accident Occurred.

To span over the central portion, the plan was modified, and the central spans increased from 200 to 245 feet. Owing to the immense weight of the girders (190 tons) for each of these spans, the artificial rock foundation was enlarged to a circular hed of concrete 31 feet in diameter. A caisson for this was 45 feet high and 31 feet broad, like a large gasholder. It was made of wrought iron, and 20 feet of it, to penetrate the rivsr bed, was stiffened with a 14-inch thick ring of hrickwork. It weighed, when floated out, 200 tons, and four hig rams were used to lower it. The sand pumps wsre used, and the interior filled with concrete.

On this platform so formed, a hexagonal pisce of hrickwork, 22 feet high, 16 feet wide and 27 feet in the direction of the current, was suhsequently fixed, hringing the structure up to ebh-tide level, and the hrick and masonry were thereafter built up a little ahovs high .water level. The diameter of the six iron columns (rising 80 feet ahovc the masonry) which constituted the uppsr works, was snlarged to 15 inches for the four central ones and 18 to the outsr ones. In the construction of these huge pisrs, in the navigahle portion of the stream, it was important to offer as little ohstruction to the current as possihle. To the northward of the 13 wide spans in the deep channel the piers, resting on a gravel foundation, were huilt on ths douhle cylinder principle, the cylinders being 15 feet in diameter.

The piers at the north curve were made of three cast-iron piles, hollow; and Mr. Brunlees devised a plan of sinking them hy pumping water down through them at high pressure, washing out the sand till they found a foundation of hlue clay.

The Iron Lattice Girders and Spans.

The euperstructure of this hridge looked at from a distance gives one the idea of very light iron-work, although it was not so considered. Wrought iron bas heen used in hridge huilding for many years, and the duty of the engineer now includes not the mere calculation of the strength of a girder, hut the selection of the system which gives the greatest strength with least waste of material. For the Tay hridge the latticed girder was employed as giving the requisite strength and *lateral* stiffness, hut the result has proven that in the latter respect an awful mistake must have been made.

To insure the quality of the material no iron was used unless it could stand a tensile strain of 21 tons to the square inch. The pieces of iron forming the girders were erected and riveted togcther on a staging near the shore, and connected to it hy a gangway. Each span had four horizontal pieces, or hooms, two at the top and two at the bottom, and four vertical posts at the ends, the hooms heing of the trough section, and varying from 12 to 21 inches in width. Nine crosses, consisting of struts and tie-hars, kept the hooms at the proper distance, and transmitted the strain to the ends to he supported hy the piers. In the case of the largest spans the struts were of the H section and in the shorter spans, of channel section. The smaller sized girders were 16½ feet deep. For the 245 feet spans, however, the two girdere forming each span were 27 feet deep, and of an aggregate weight of 190 tons; and the work of erecting and riveting them on the staging required four weeks to accomplish, about 18,000 rivets having to he put in each. One of these epans heing completed, part of the staging was taken away at either end, harges were then introduced iuto the gaps and at high water the mass of iron-work was towed out and moored in position. Ae the tide fell the girders settled in the piers and the harges were then withdrawn.

The raising of the girders was effected hy means of hydraulic apparatus, placed on stages holted hetween the colnmns, and the services of 80 men were required to raise the span 20 feet per day—the usual rate of progress.

Expansion and Contraction of the Iron.

In construction of the girders due provision was made for expansion and contraction of the iron, which is reckoned at 7 feet over the whole length of the bridge. The spans were arranged in eets of four, five and six, each set having its own fixed and expansion bearinge, admitting of eelf-adjustment at 21 different places. In each group only one of the pieces is firmly fixed to the superstructure; the ends of the girders meeting on it being firmly bolted down; while at tbe other piere of the set the girders rest on rollers over which they can elide when expansion or contraction takes place, according to varying conditions of temperatnre. To defects in eome of the details in this part of the arrangement some persons attribute tbe accident that occurred, fearing that due provision was not made for lateral strain caused by the high winds. At the inception of the work, however, this point was thoroughly discussed; and indeed, it was on account of the prevalent high winds that many did not believe the bridge would stand. The engineers therefore had warning enough on this point to have exercised the greatest care.

It is a fact, however, that experience proved they by no means allowed sufficient margin for elemental forces to be encountered in the progress of the work, and the promoters proceeded on data which subsequently proved inaccurate in eeveral essential particulars. It will now he said with reason, that the engineere followed in their footstsps. As to the weather, sometimss they only had five or six days a month in which they could work. In the winter of 1874, for three months no work was done ontside the jetties. In 1876 two electric lights, each 1000 candle power, wers hrought into operation to forward the work, and the men worked by night as well as by day. The first train crossed the hridge in September, 1877, hut it was not formally opened until May, 1878, when appropriate ceremonies were held. Before that, however, six locomotive engines and tenders, weighing 438 tons, wers passed over to prove the psrfect stahility of the structurs.

Several Accidents

Occurred while the hridgs was huilding, as would of course hs the case with from 500 to 600 men at work. Several of the cylinders capsized from ths irregular hottom; the air-hell and engine were thrown into the water. At one time while nine men were excavating the sand, the cylinder exploded, killing six of them. A searching inqniry was made, hnt ths exact cause of ths explosion was nevsr ascertained. During a heavy gale in February, 1877, two of the largs spans and one girder of 145 feet span adjoining them, together more than 400 tons in weight, were hlown down. Ths iron part of ths piers on which they were supported was complstely wrecked. Only one man was killed, although 40 men were on a girdsr near hy which was hsing raised, and had to stay there all night in the gale. Anothsr time a girder, heiog floated out on the harges, hroke away from the tugs in a gale, and, although drifting around all right, was saved next day. A striking illustration of the adhesivs qualities of cement may here hs cited, as shown in the case of the pillars huilt of hrick, set in cement, which were overeet and then fished out. Although only huilt two weeke previous, they acquired the solidity of rock, and it took dynamite to hreak them up.

In the constructton of thie hridge there were nsed 3,520 tons of cast iron, 6,281 tons of malleahle iron, 90,600 cuhic feet of lumher, 8,600 tons of cement, 4,350,000 hricks, 27,000 cuhic feet of dressed ashlar and 355 cuhic yards of rough ashlar.

Hight of the Piers and Girders.

The deepest part of the river is ahout 2,200 feet from the Fife ehore, where the depth at high water during spring tides is from 40 to 45 feet. The rise and fall of tide varies from 12 to 17 feet, and the current in that part of the river is ahout fonr miles an honr. The greateet hight of pillar occurs at the first of the wide spans on the south side, the extreme hight from the foundation in the hed of the river to the underside of the girdcr heing 142 feet. Adding to this the depth of girder, 27 feet, gives a total of 169 feet—figures which help to convey an idea of the stupendous character of the work.

The permanent way is of donhle-headed eteel rails, and provided with guard rails. The floor of the bridge hetween the longitudinals is of three-inch plank, covered with a waterproof composition. All the ironwork is coated with hlack varnish to preserve it. There is also a suhstantial hand-rail for the inspectors, and a tuhe carrying 13 telegraph wires.

The Stations.

The esplanade gronnds connected with the hridge are magnificent in character. A tidal hasin was filled in, a viaduct 1,020 feet long, and 4,000 feet of five-foot thick retaining walle huilt; on it a splendid station and platform, magnificent goods-shed, hydraulic huildings, etc., while there have been laid down on permanent emhankments upward of ten miles of railway. The goods-shed is 400 feet long and 150 feet wide, huilt of wood, iron and glass, there heing over 70,000 square feet of glass in the roof. The passenger station ie 380 feet long, heantifully huilt, with an iron roof, fully glazed. An 1,880-foot tunnel, 25 feet wide and 16 feet high, also connects with the station.

Notices of Recent Patents.

Among the patents recently ohtained through Dewey & Co.'e SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

RAILROAD CHAIR.—John R. Sullivan, San Rafael, Cal. Patented Dec. 30, 1879. No. 223,187. This invention relates to that class of railroad chairs wherein two chairs and a connecting metal bar serve to secure the track, the object of which is to provide such a chair as will give a broad eustaining surface to the rail, and yet greatly cheapen its construction. The rail-supporting bases are of cast iron, and in form like a parallelogram. The upper side is made to slope in each direction from the line where the rail crosses it to the outer end, and these inclined faces are grooved so that a large base may he obtained without undue weight. Each pair of bases are united by means of a wrought iron bar which has its ends laid into the mold so as to he cast with them. The top of the base has a douhle elot formed across it, the outer side of one slot having its hottom of the hight at which it is desired to have the base of tbe rail stand, and is beveled under the outer face so that one flange of the rail will be in this groove. The inner part of the slot has its bottom lower than the plane of the upper slot, and the meeting edge hetween the two is inclined and dovetailed or beveled downward and backward. A key is formed so that when in place its contour will he and form a part of the base. The whole forms a cheap and convenient railway tie.

PATENTS AND INVENTIONS.

List of U. S. Patents Issued to Pacific Coast Inventors.

[From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING DECEMBER 30, 1879.

223,102.—ORE SEPARATOR—C. Bennett and P. Burnham, Silver City, New Mexico.

223,028.—CHECK-HOOK—W. M. Blain, Salinas, Cal.

223,114.—MACHINE FOR TARRING WIRE ROPE—R. Cotter, Virginia, Nevada

223,032.—FILLY PLATE—C. Creiger, Comanmes, Cal.

223,187.—RAILWAY CHAIR—J. R. Sullivan, San Rafael.

223,082.—HAY UNLOADER—J. Tyler, Milford, Cal.

223,203.—VEHICLE AXLE—E. A. Wiblo, Folsom, Cal.

7,788.—MEDICINAL COMPOUND—Trademark—Dr. Val. Sechner, S. F.

2,172.—CHOCOLATE—Label—E. Gulttard, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

News in Brief.

THE composer, Wagner, is seriously ill.

A TERRIBLE famine provails in Armenia.

THE famine in Northern Persia is increasing daily.

EX-EMPRESS EUGENIE will visit Zululand in February.

GREAT damage is being done in Franee by inundations.

THE puhlic deht was roduced in Deccmber $4,251,217.

THE Socialistie Congress adjourned *sine die* at Pittsburg Jan. 1st.

LAST year was the most prosperous in the history of Colorado.

THE death of Jonathan Reed, an old Oregon pioneer, is announced.

GEN. GRANT left Savannah, Ga., Saturday last for Fornandina, Fla.

OVER 100 Nihilists have been recently arrested in Warsaw, Russia.

DE LESSEPS was received with great warmth on his arrival at Panama.

THE new California Supreme Court organized at San Francisco on Monday.

CHARLES L. BUOBEY, the well-known architeet, died at Oakland receotly.

PARNELL arrived at New York Jan. 2d, and was appropriately received.

THE country hetween the Volga and Don, in Rnssia, is famine-stricken.

COMPULSORY education is heneeforth to he a feature of the government of Cuha.

SEVERAL survivors from the lost steamer *Borussia* have arrived at Baltimore.

THE navigation of Fraser river is being improved hy tbe removal of rocks.

CHARLES P. LELAND, "Hans Breitman," will visit California in the spring.

BISHOP GILBERT HAVEN, of the M. E. Church, died at Malden, Mass., Jan. 3d.

SERIOUS disturhances have occurred in Brazil on account of the levy of new taxes.

DURING 1879 specie was imported into New York to the amount of $84,260,405.

DURING the last fortnight the Afghans have lost 3,000 men in killed and wounded.

IN New York during 1879, 460 failures were reported, with liahilities of $16,383,932.

COUNT JOHANNES, a well known character on the New York stage, died a few days since.

CHARLES MORGAN, who recently died in New York, left property valued at $12,000,000.

DRIFT ice in the Seine has caused much damage at Paris, and the river is full of wreckage.

A WOMAN attempted to murder a son of Senator Morgan, of Alabama, in Washington Jan. 1st.

A BITTER fight is progressing at Washington against the reappointment of Governor Emery, of Utah.

ABOUT 200,000 pounds of alfalfa seed have been shipped from San Bernardino county this year.

FOUR persons perished in a fire on Friday last at New York, and five others were hadly injured.

IT is denied from St. Petersburg that the establishment of a Regeney in Russia is contemplated.

ONE man was killed and two others severely injured on Thursday Jan. 1st, near Napa, hy a railroad train.

THE famine in the province of Upper Silesia is so severe that people are selling their children for food.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the hack files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce, and valuable for future reference and library use.

INSURANCE.—We refer to the announcement in another column of the old and well-known fire and marine insurance firm, Hutchiusou & Mann, of No. 322 and 324 California street. They represent twelve companies, with an aggregate capital of $28,000,000.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruher's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

SETTLERS and others wishing good farming lands for sure crops, are referred to Mr. Edward Frishie, of Anderson, Shasta County, Cal., who has some 15,000 acres for sale in the Upper Sacramento valley. His advertisement appears from time to time in this paper.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Atlanta Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, West Tintic Mining District, Juan County, Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the Second day of January, 1880, an assessment (No. 1) of Five Cents per share was levied upon the capi al stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, No. 420 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Fifth (5th) day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Friday, the Twenty-Fourth (24th) day of February, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

By order of the Board of Directors.

A. F. MCGREW, Secretary.

Office—Room 7, No 420 Montgomery street, San Francisco, California.

Butte Hydraulic Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 2) two levied on the Thirty-first day of October, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
E Poirson	13	2½	$25 00
L Lapierre	22	2½	25 00
H Marcoux	24	2½	25 00
J B Lussier	25	2½	25 00
John Britt	26	2½	25 00
Geo W Deltzler	37	5	50 00
N Desautelle	41	2½	25 00
Jos Lucier	42	2½	25 00
N Coldtree	43	7½	75 00
Geo Moreau	44	5	50 00

A M Wilder, Trustee	1	10	100 00
A L Lengfeld	5	5	50 00
L L Dennery	6	5	50 00
W E Lutz	7	5	50 00
Geo. H. Powers	11	5	50 00

And in accordance with law and an order of the Board of Directors made on the 31st day of October, 1879, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the company, room 3, No. 220 Sansome street, San Francisco California, on Monday, the 22nd day of December, 1879 at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

L. L. DENNERY, Secretary.

Office, room 8, No. 220 Sansome St., San Francisco, Cal.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock of the Butte Hydraulic Mining Company is postponed to the Fifth day of January, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock is postponed to the second day of February, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

San Francisco, Cal., January 8d, 1879.

Gover Mining and Milling Company.—

Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given that at a meeting of the Directors held on the 24th day of December, 1879, an assessment (No. 40) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the second day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the First day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale

W. O. WILSON, Secretary.

Office—402 Front street, room 6, San Francisco, California.

Mariposa Land and Mining Company of

California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 10th day of December, 1879, an assessment (No. 17) of Fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency to the Secretary, at the office of the company, room 33, Nevada block, No 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 10th day of January, 1880, will be delinquent and advertised for sale at public auction; and unless payment is made before will be sold on the 2d day of February, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors. LEANDER LEAVITT, Secretary.

Office—Room 33, Nevada Block, No. 309 Montgomery St., San Francisco, California.

Numa Mining Company.—Location of Prin-

cipal place of business, San Francisco, California. Location of works, Humboldt County, Nevada.

NOTICE.—There is delinquent upon the following described stock on account of assessment (No. 2) levied on the 23d day of October, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstaoding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

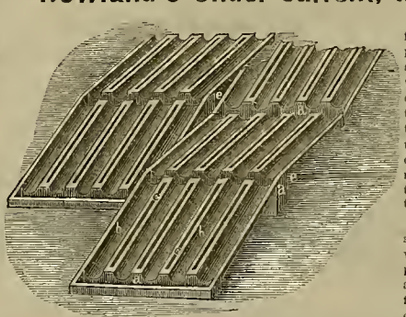
Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

Howland's Under-current, Mill and Sluice Riffle.



This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

Evans' Amalgamating Riffle.

A New Device for Saving Fine Gold and Sulphurets.

In 1868 Georgs R. Evans, a miner of many years experience, invented and patented a gold-saving apparatus which was known ae "Evane' Corrugatcd Riffle and Undercnrrent Sluics," the merit of which brought it into nse in many placee with good eucceee. In following up his experimente in thie direction, he had an excellent opportunity to etudy the effecte of ths concentrating action of peculiarly obstructed currents of water, and to improve hie original idea; having all the time ths object in viaw which has eludcd eo many inventors, thet ie, eaving all the finest particlee of precioue metale, concentrating and catchiug ths eulphurete, and, equally important, prsventing lose of quicksilver.

The experience of thees yeare is embodied in an improved riffle constructed on practicel principlee and for which suitahls etepe have been taken to securs letters patent.

The accompanying engraving will give an idea of ths general appearance of the apparatus, as arranged to connect with the battery of a quartz mill. By ueing suitable screene, the riffles may of couree he ueed in placer mining or in any work where precioue metals ars to he eaved.

All minere understand well enough that ths battery and plate amalgamation of quartz mille ie hy no meane perfect, and that coneiderahle loee of quicksilver and fine gold occure. Ths ordinary flat inclined amalgamating plates are defective in this respect, that through ths gravity of the quicksilver with which they ars charged, accelerated hy ths downward current of water and pulp, and ths jarring of the etamps, more or leee amalgam is detached from ths plates and peeces off. The finest of ths particlee of gold, which will float on ths eurface of ths current of ths water never reach ths plate at all, eo do not coms in contact with the mercury. Then the material passee over inclined blanket slnicss, flat like ths plates, eo that ths hlanket threade will catch the eulphurete and any fine floating particles of gold which have eecaped ths plates. The effectivenese of the hlankete ie in a great measurs neutralized hy ths nap of the hlankete heing flattened hy ths current. It is not only in quartz mining theee losses occur, hut in placer and hydraulic work ths fine gold paeses off with the tailinge, and efforte to save the sulphurete or platinum havs hesn ahandoned as futils.

It is theee difficultiee which the Evane' riffle ie designed to overcoms. Ths peculiar feature of thees riffles is ths undulating eurfacs over which the water and material under treatment flows, and the curioue and effective action dus to the form, by which a euccession of dead-water eddiee occur in the current; thees eddise forming at ths loweet pointe and in ench a poeition as to retard and etay the onward progree of paeeing particlee of gold, amalgam or mercury.

Ths eeries of amalgamating riffles ars of any width and any numhsr or length, of an undulating surface, mads hy the union of alternats reverse curves of ehallow dspth, so that when the current flowe over the ridgee it will pass down into ths hollows and creats a sort of rolling movsment or eddy, hy which thesand, gold, etc., ars rolled over and ovsr and brought into contact with the amalgamating surface. This action, aleo, to a certain extent ecours or brightene any "ruety" or coatsd gold so that it will mors readily amalgamate. In paeeing on to the surface of ths platee the current paseee over ths ridge into the hollow or concavs, where it hreake and forms a riffle or wave, with a very effective and peculiar reflex action. Ths material which ths current carriee, ie, at this point, brought hy ths roiling motion of the water—the eddy or wave—into contact with ths platse and any fine gold or floured quickeilver ie caught.

The lighter material ie then carried on over to the opposite slops, and ths current, again flowing smoothly in ite normal condition, carriee ths material over the euceeeding ridge into the next depreeeion, where the operation is rspeated, and eo on down to the end.

Thsre ie not the chancs for ths loes of quicksilvsr ae in flat platse, eince each depreseion servee as a receptacle, from which, in ordsr to escape it muet, in the firet place, move out of tho dead water againet the rcflex wave or riffle, and muet also travol up an incline, noither of which can it very readily do.

Thie "riffls" is eomewhat different from what ie implied in the ordinary acceptation of the tsrm. It ie not a rigid traneveree bar or obstruction, ahovs the enrface, designed to intercept ths onward progrsse of flowing material. It is a water riffle, an elastic check, in constant and ceaselees motion, hut more effective in retarding the progress of the precioue particlee. Ths current ie not suddenly checked, and the water agitated hy a rigid obetruction, tending to activcly dieturh the molsculee, hut the wave forme naturally, and a water riffle ie the consequence. Thie water riffle, hy ite constant ehaking and agitation, hae a concentrating action, similar to that brought ahout hy ehaking a pan back and forth, hy which the lighter worthleee particlee are eeparated and allowed to flow off, whils the heavier precioue particles are retained under and within it. The material is not stopped *above* the riffle, hut *in* it, and oncs etopped, is held *under* it. The shaking of the water riffle, caueed hy ite particlee heing conetantly changed ae new onee coms and ths othere paee on, hae the effect of preventing packing of ths heavy material undsr the riffle in the hollow where it forms, eo a continual concentration eneuee, the gold and quicksilver heing shaken down to the amalgamatsd surface hslow any hlack eand.

It will hs seen that no euch action ae thie ie poeeihle in a rigid traneveree riffls formed of wood or copper. In the first placs the material cannot get under euch a riffle, which, moreover, is liahls to let ths eand pack above it; and there is no concsntrating action at all. Ths wave riffle cannot he formed on a plans eurface without the ues of rigid traneverss hare, hut forms naturally in ths undulating surfacs deecribed.

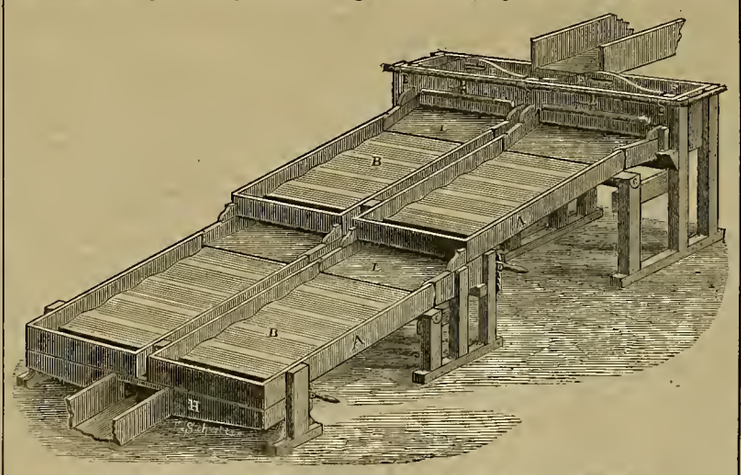
For attaching to the hatteriee of quartz mills, the undulating riffiee, *B*, are placed in a suitahle frame, *A*, at the head of which is a distrihuting box, *F*, this hox receiving its supply of material from a central source and extsnding across the upper or amalgamating series of riffiee. The hottom of eaid hox is deeper than the inclined plate at the head of ths firet riffls, to ineure an even overflow of the material. This hox is provided with a epreader eo ae to dietribute ths material received through the openinge along the eaid box. Ths hox is aleo provided with gatee, *E*, eo that the matsrial can he gauged to any deeirahle quantity over the amalgamating rifflee. A ehort inclined plane, *L*, allowe the current to flow with an even surface into the firet depreseion.

The plates ars arranged in ehort douhls eections with a drop hstween ths pairs, as ehown; it heing found that they work hetter in ehort than in long eections. At the lower snd of the lower eection is a trough, *H*, into which ths waets matsriale fall. Thie trough tapere or conversges to a common centsr, eo that ths whole of the refnes and water can he conveysd to any desired point. Thie trough, however, is usually eet helow ths hlanket eectione. Anothsr eeriee of riffles of the eame undulating eurface as deecribed, ie set below the lowest eection of amalgamating platee; hut thie eeriee is lined on ths eurfacs with a hlanket for concentrating and saving eulphurete, platinum, etc. The peculiar action of ths current in forming a revolving eddy, as deecribed in ths amalgamating eeriee, caueee the nap of the hlankete affected by thie action to attain an upright position, thue preeenting to the precioue particles a more eecure lodgment. The elastic water riffle is here again formed in the hollows or depreeeions, ths concentrating action of which is very effectivs to eave the sulphurete.

The angle of inclination of any of the eeriee of rifflee may be regulatsd hy ths levers, *D*, ths upper end of each eeparats eeriee reeting on a rocking bar, *C*, as shown. The inclins of the riffle eections ie thue regulated to euit the clase of material treated, or ths amount of water aveilahls. A great deal of water with a elight incline, or considerahls incline with littls water, may hs used. Thie ie especially useful in clcaning up, ae any miner will eee.

When it is deeirsd to clean up any one of ths rifflee ite gate, *E*, will hs oloeed, and ths water may he turned into ths head of ths riffls from ths perforated pipe, *I*, eo that clear water is paseed on to the platee.

In cleaning up the hlanket sections, clear



EVANS' AMALGAMATING AND CONCENTRATING RIFFLE.

water ie allowed to run on, and ths sulphurste, etc., may he ewept down with a hroom into the trough, *H*, and thsnce into a tank.

To maks the rifflee in ths shape shown, wooden forme are firet prepared, and upon them ars placsd silver-plated amalgamated platss, all so arranged in the hoxes, *A*, that no leakage can occur.

A eet of theee wave-line platee and blankst eluicee hae hesn est up for uss in ths haesmsnt of No. 416 Clay etreet, for eeveral weeke past, whers thsy havs heen tseted and examined hy numhers of mining men and experts. Ths operation can thers bs clsarly seen, and it ie very intsresting to watch ths curioue action of the elaetic water riffle in concentrating ths material and hiding ths valuahle portions within itsslf. S. P. Taylor and Alexander Lewthwaite ars intsrseted in the apparatue with George R. Evans, the inventor, and either of thsm will he pleaeed to ehow it at work to any mining msn dsirons of examining it.

THE Mayor of San Francieco hae recsived a diepatch from ths Lord Mayor of London, asking aid for an international teetimonial to ths memory of Sir Rowland Hill, ths author of ths penny poetags system.

THE Legielature of Arizona has organized—Council, four Dsmocrate and nins Republicans; Houss, thirteen Dsmocrats and thirtesn Republicane.

HON. L. Q. C. LAMAR, U. S. Senator from Miseissippi, is suffering from a stroke of paralysis.

The San Francisco Copper Mining Company's Mine and Reduction Works.

The San Francieco Copper Mining Company and Reduction Works ie eituated in Nevada county at the altitude of about 400 feet abovs ths lsvel of ths eea. An ahundancs of timher is in close proximity to the mine, and water pewer can he had for sevsn monthe in ths year fres of charge, and afterwarde from ditchee in the neighberhood.

The mine is 12 milee from Wheatland on a branch of the C. P. R. R. and a good road leads from there to the mine. Wheatland ie 140 miles from San Francisco; heeidee, ths mine is 18 miles from a navigahls point on the Feather river.

The company hold 3,000 feet on the vein, and two mill-eitee covered hy United Statee patent. The vein is almost vertical with a elight inclination towards the eaet, and its coures is nearly northwest and eoutheaet, and is imbedded in a crystalline elate on ths west, and granits on ths eaet.

A ehaft has been eunk on the east wall to the dspth of 150 feet through a solid hody of ors. At the depth of 60 feet the firet croeecut to ths west developed a eolid vein of mundic ore 75 feet in width, undieturhed by any fault; ths ore on thie levsl averaged 7%.

At 100 feet another croeecut wae run to ths wset, and ths vein proved the eams in width. From thie level the reduction worke are at preeent eupplied with ore, and the averags of the eams hae improved to 9%.

The roasting of the ors ie done in open pilee, from 1,000 to 1,200 tons hurning four to eix months.

The leaching of the eulphate formed in roasting is performed in wooden tanks, from thess the solution is traneferred to rseervoirs to eettls, and afterwards pumped into rsvolving cylinders.

The precipitation ie affected hy meane of ecrap iron, aud after two or three tone of precipitate of copper has accumulated in each cylinder, ths eame ie discharged, filtered and traneferred to a drying pan, which ie heated hy the exhauet eteam of ths engine.

After drying the precipitate or cement copper, it ie ready for market and aesaye hetween 85% and 90% fins.

From 40% to 50% of the copper ohtained ie extracted from ths ors immediately, and ths halancs is gradually ohtained from tho dump pile, whers the ore spontaneously decompoeee.

Amount of coppsr ore manipulatsd and cemsnt coppsr produced from January 1, 1879, to January 1, 1880, ieae follows: Ors manipulated, 6,000 tone; cement copper produced, 512,128 pounds. Thers is at preesnt 15,000 tons of ors roasting, and the works havs a capacity to work 60 tone daily.

During ths laet four years 17,000 tons of waets ore havs accumulated on ths dump pile, which still containe a produot of 64% of red oxids of iron, and ths quality ohtained from sams hy crucihls emelting hae heen equal to the hest of white iron.

Sulphuric acid could he mannfacturad at a nominal cost of three-quarter cent per pound from ths fumes of 15,000 tons of ore waeting themeelves in the air.

Ths company during the year 1880 will be prepared to supply any rolling mill which may he etarted with oopper at Eastern pricee, and the amount of ors at preeent in eight, eubject to competent inspection, will fully warrant ths expenditurs needed in the conetruction of ths rolling mill.

Ths eituation and reeources of thie mins, and immense hody of ors now in sight, maks thie a property of great valus. It requiree only ths proper applicatione to work up the differcnt metale and acids which ths ors contains.

THE Stats Lsgislature of Missiesippi ars endeavoring to slect a U. S. Senator to eucceed Bruce, the colored membsr from that State.

THE father of Prof. Richards, of Yale College, wae killed Friday laet at Stamford, Conn., by a railroad train.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds

Globe District, Arizona.

Editors Press:—Here I am at Globe again, after a three weeks' absence, and I find during that time there has been a marked improvement; several new strikes and a better and livelier feeling throughout, which has started work that for a long time has been shut down. Advices have been received that the machinery for the Mexican and Nugget mill has been delivered at the terminus of the railroad. Teams have been dispatched, and by the time that is hauled they will have to return for the Irene mill. The grading of roads and mill sites, together with the developing of the respective properties, make employment for nearly all who wish to work. The rebuilding of the Miami is nearly finished, as also the remodeling of the Champion, so that in a short time our capacity will be increased from 5 to 50 stamps.

I have, since my return, visited several of the new strikes, and I found that at the Irene the shaft, at 90 feet, was in solid ore of a high grade. The indications are that the ore body now is considerably wider than the shaft. This shaft was sunk for an air shaft, which will be connected with a tunnel now being driven in to tap the vein nearly 250 feet deep.

At the Buffalo and Mark Twain, I found the shaft had cut through the iron and copper capping, and that silver was predominating. This is one of our strong veins which was capped to the depth of about 40 feet with base metal; this having been gone through, it is now developing into a fine property.

The Alice and Alice Southwest lie to the south of the Buffalo and Mark Twain. One has been prospected to the depth of 175 feet, the other 100 feet; both show ore bodies of a high grade, and enough to warrant the building of a mill.

Report comes that some rich strikes have been made in the gold belt, which I will try and visit before my next. This belt is situated about six miles northwest of Globe, and has some fine prospects, among which is the Golden Eagle, recently purchased by Eastern men. The ore averages from $35 to $65 per ton, free gold. Twenty-eight tons taken from the Eagle returned $1,476.45. These parties have bonded seven other prospects in the same belt, and the building of a gold mill will soon take place.

Eastern men are about the only ones who are doing anything here, and all who have visited this district are well pleased with the present showing. I am satisfied that this district will soon have several good-producing and dividend-paying mines. Miner.

Mining in San Bernardino County.

Ivanpah Mining Camp.

Editors Press:—In the first place allow me to congratulate you on the great advance you have made in your paper the past four years, especially as to the mining interests. I am glad to see that you have steered reasonably clear of the scientific gulf. The average miner and prospector cannot understand a too scientific paper, and besides they wish a more practical knowledge of things in general. I and many others have noticed with pleasure the stand you are taking regarding, among other things, the development of the copper interests on the Pacific slope.

Clarke Mining District.

Better known as Ivanpah mining camp, is within about 12 miles of the State of Nevada, and about 200 miles from San Bernardino, where they get their supplies from. This camp has been worked continuously since 1870, considerable money having been taken out of various mines, notably, that of the McFarland Brothers, now incorporated as the Ivanpah Con. Mill and Mining Co. of San Francisco. There are two mills here, one belonging to the last named company, and one owned by J. A. Bidwell.

The district and the surrounding country is composed of a large number of silver ledges, principally worked by chloriders. Since the incorporation of the

Ivanpah Con. Mill and Mining Co.,

With W. O. McFarland as its Superintendent, the camp has been given quite an impetus. The mill is being thoroughly overhauled, and the mines are being opened up in a more practical manner. The company has the best defined ledges in limestone that your correspondent has ever seen. The claims had been worked formerly by the McFarland Brothers, who took out a large amount of money. I might call it only surface working, as the deepest shaft is about 200 feet. I was accorded the privilege by the Superintendent of examining the old works, and was greatly surprised to find so well a defined lode, work having been done for over 2,500 feet in length, showing a large number of chutes of ore.

In one of the tunnels the ore chute is over 300 feet in length, the vein being small but very rich. There are some two or three men stoping on this ore chute. They are also sinking two shafts, one about the center of their claims, which is down about 135 feet, showing rich ore at the bottom of the shaft. I was shown the return of the workings of the ore from this shaft. The first-class ore worked $1,110, and the second $340.50. The other shaft is being sunk 150 feet lower down to the west, showing the same well-defined ledge. I understand that it is the intention of the company to sink this shaft at least 250 feet more. I think there can be no doubt of the permanency and paying qualities of these mines.

There are a number of other mines in this district paying the owners a handsome profit. The Alley mine, about one-quarter of a mile to the northeast of the Ivanpah Con., has shipped quite a quantity of ore to your city, averaging about $1,500 per ton, the second-class being worked here. One great drawback to the camp heretofore was the excessive price of milling; the charges being $50 per ton, 5% shrinkage and 80% of proceeds of bullion.

About eight miles south of here quite a number of rich strikes have lately been made, assaying from $150 to $5,000.

Gold has also been found about two miles from the Ivanpah Con. mines. A number of locations have been made and work commenced but they are not sufficiently developed to be able to judge whether they will pay. I have seen some very rich specimens taken out during the week.

The wages of the camp for good miners are $4 per day. Board $8 and $9 per week.

It would appear to me, that the San Francisco papers have somehow overlooked the mining interests of this county. This is a splendid mineral-bearing range of mountains and only lacks the capital to make itself agreeably known. I will drop you a line about the surrounding country shortly. J. B.

The Mono County Mineral Belt.

Editors Press:—After spending 10 months in an examination of the mineral belt from Laurel district on the south to Tioga district on the north, I am fully satisfied that the wealth and importance of this new mineral belt will soon attract great attention. This belt is some 50 miles in length, with an average width of about four miles. It is situated on the eastern slope of the Sierra Nevada range, in Mono county, Cal., the course of the belt lying northwest by southeast. The veins are wide, and though the assays are low on the surface, they increase in value as depth is obtained.

The names of the districts lying along this belt are, Laurel district on the southern end, Lake, Prescott, Tioga, Homer, North Fork and Castle Peak. The mines of

Lake District

Are opened to the greatest depth. Mammoth company have opened their ore body at a vertical depth of 600 feet. At this depth 20 feet of ore nearest to footwall mills $40 per ton, the remaining 37 feet milling about $12. They have already completed a 40-stamp mill. Everything is being placed in good order, and shortly the owners will receive handsome dividends. This mine is rightly named; it is indeed a Mammoth.

The True Blue company, south of Mammoth, are opening their ore bodies by tunnels from the east side of Mineral hill. One tunnel completed 350 feet has penetrated the vein, and is now in ore about 40 feet, mostly low grade, but increasing in value as the footwall is approached. This mine has two veins crossing the property, the east vein being now opened by tunnel, while the west vein is opened by means of a shaft on the mountain. The True Blue company have purchased 80 acres of land at the base of the mountain for mills which will be erected the coming spring.

Headlight and Monte Cristo are opening their ore bodies by a joint tunnel on the western slope of Mineral hill, which will be completed some time in May. A shaft has been sunk 150 feet in the mountain on the vein, showing a true fissure vein, 13 feet in width carrying good ore.

Don Quixote, adjoining True Blue, is also being opened by a tunnel from the slope with flattering prospects.

Metallic Con., on the south, have a fine property if developed, the ores showing much fine gold.

Lake Vein company have promising mines, but not yet developed sufficiently to show their true worth.

Silveropolis, Crescent, Last Glimmer and others are preparing for active operations in the spring.

The Pioneer company have a most excellent property, but little worked as yet.

Three towns lie around the base of the mountain—Mineral City, Mammoth City and Pine City. Mammoth is the principal town, having a population of about 1,500, and is the base of supplies for a large region of country. The surrounding country is well timbered and water is found in greatest abundance.

The next important districts are

Tioga and Homer

Situated directly west of Mono lake, at a distance of twelve miles. The mines of these districts are rich in precious metals. There are two distinct mineral-bearing belts running parallel with each other—the eastern belt carrying gold, the western silver and the baser metals.

The west zone or belt passes on the western side of Mt. Dana, showing one large, strong fissure vein. I measured width of Golden Crown location and found some 200 feet, between walls, filled with ore strata. Ore taken near the surface gave assays of from $30 to $200 per ton. These mines may be reached with facility by means of a road from Yosemite valley; distance twenty-five miles. There is an abundance of wood and water at the mines.

The coming summer will change this region from a solitude to a scene of bustling activity. Thousands of miners will congregate here, mills will be erected, and the noise of stamps heard.

The Wealth Enclosed in these Mountains Must be brought forth; cities will spring up along this whole mineral belt, from Bodie on the north to Mammoth on the south. Two toll roads are now building which will open these mines from the west—one commencing at Fresno Flat, running to Mammoth City; distance fifty-two miles; the other from Sonora to Tioga, following the Tuolumne river; distance sixty miles. This mineral belt has for its base on the west solid granite, on the east porphyry and slate. Between these different formations rest the lodes or ore channels of quartz gangue, constituting what are known as contact veins, and furnishing unmistakable evidence of permanency. The belt lies west of the volcanic region about ten miles, and follows the older granite which lies west. The volcanic eruptions have spent their greatest force near Mono lake. The whole region is one vast bed of ashes and lava, with huge mountains of basaltic rock. The mineral lies west of this disturbed section in a more permanent formation. Nearest the volcanic region lies the gold belt, then the silver and base belt; gold on the eastern, silver on the western slope of the mountain.

The belt most permanent is the silver, the gold appearing to be much scattered and in pockets, with the formation broken on the surface. The silver belt is permanent, shows but little disturbance, and is the most reliable. The expense of a trip from San Francisco to these mines in the summer is $15 by S. P. R. R. to Madera, thence by stage and saddle train, two days being consumed in making the trip.

A. Caldwell.

The Hofmann Process.

Editors Press:—In a recent issue I find an article on an alleged new process of treating silver-bearing gold sulphurets, by Mr. Hofmann, consisting of an application of the Patera preceding the Plattner process, with salt roasting, as introduced by me at the Eureka mine, Grass Valley, in 1865.

Having experimented on several occasions since 1876, with this modification of the usual method of Plattner before Patera, which modification at this late date aspires to the dignity of a new process, I can say, that in my hands both methods gave equally as good, or in other cases, as *poor* results on such argentiferous gold ores as I treated, with the advantage in favor of the Plattner-Patera against the Patera-Plattner method on account of greater simplicity of the former.

Great care, however, must be taken when the Plattner precedes the Patera, to collect *all the gold of the solution*, especially when the ore carries copper.

I would call Mr. Hofmann's attention to several piles of sulphuret tailings in this State, assaying from $12 to $18 per ton in gold, the ore having been previously treated for silver by the Patera, from which scarcely a *trace* of gold can be extracted by following it with the Plattner process. G. F. Deetken.

The Locomotive.—A correspondent of the *American Machinist* writes: Thirty years ago it required 1,800 days' labor to construct a locomotive; now it will not exceed 1,500, and a far superior machine in every respect. There are 16,000 locomotives in the United States, and there are over 2,800 different pieces in each, all of which will have to be renewed every 10 or 12 years. Locomotives that retain their identity 20 years or more, as claimed by some roads, are something like the boy's jack-knife which he had 10 years, but it had 9 new handles and 13 new blades. The present capacity of all the shops is not far from 1,700 locomotives per year, and the different roads build in their own repair shops about 100 more, making 1,800 a year in all. Now, allowing 15 years as the average life of an engine, you will see that the shops can build 27,000 in the meantime, showing that the present capacity of our locomotive shops need not be extended for a long time to come.

Electrotyping Applied in Making Statues.—The practical problem of reproducing a large clay model in bronze by the electrotyping process instead of casting, has at last been successfully accomplished in Belgium. The papers report that the Electro-Metallurgical Company, of Brussels, has completed a colossal statue in bronze of Jan Van Eyck (the great ancient painter who invented the art of painting in oil colors), by the system of electro-deposition. The galvanic process occupied several months, although a thickness of but six to eight millimeters (about one-third of an inch) was attained. It is the largest article which has been produced by this method, being over 12 feet in hight, and is necessarily a much more perfect imitation of the model than could be obtained by casting.

Cause of the Decline in Silver.

The value of silver bullion is an item of no inconsiderable regard when the product of the silver mines of the Pacific slope is taken into estimation. The gross weight of the silver yield when divided into ounces, the standard of weight for the market quotations, is so great in numbers that the variation, either of advance or depreciation of a fraction of a cent in the ounce price, produces a marked change in the profits of the mines. Owing to a combination of causes, silver depreciated in the London market from 1874 to 1877 from 59d to 47¾d, being a decline of nearly 20%. So great a decline was sure to produce an injurious effect, by reducing the profits on one of our most prominent industries to that extent. It was a depreciation of from $1.29 to $1.04 in bar silver. It was unlooked for. It was an anomaly in silver transactions. It retarded our mining interests to the extent that it reduced the profits on the outcome of the mines. It was as much of a loss to the nation as if that amount of silver had been destroyed or annihilated. It could not be regained—the loss was total.

When the storm has passed by, the ruin that it has caused has to be estimated, and the subject is studied with a view to guard against future losses from the same cause. It is well, therefore, to investigate these causes and to throw such light upon the subject as will enable us to meet another storm, if it should come, with less loss to ourselves.

The bankers of Europe have always maintained a preference for gold over silver. It is less cumbersome to transport. It can be more speedily counted. It occupies less space in the vaults. So long as public attention was not awakened to the matter, or public interest plainly affected, it was an easy thing for the financiers of Europe to quietly disburse their cumbersome silver and absorb the gold in its stead. This they continued to do until the plenitude of silver and the scarcity of gold called direct notice to the manipulation they were conducting. But this attention was awakened when the storm was raging, and it was then too late to stay its ravages.

At this juncture they, the capitalists of Europe, influenced the governments there to demonetize silver. In doing this they violated one of the great natural laws of finance, and produced a grievous evil by such violation. It disturbed the current of trade. It produced panic and distress. It destroyed confidence, and brought about an enormous shrinkage of values.

Our civil war produced a cotton famine in Europe. While this existed, India absorbed all the surplus silver which was sent there to pay for her cotton. The price of cotton and its fabrics rose to an unprecedented figure, and called for corresponding shipments of silver to southern Asia for the raw material. Gold coinage is unknown in India. Silver is her only coinage. She uses in ordinary times over sixty millions of dollars in silver to maintain her coinage, ornaments and the various uses to which silver is applied; also to compensate for the hoarding of it, such as always takes place among semi-barbarous people, and where there are no public depositories for its safe keeping. She is now sending back to Europe gold in payment of her needed supplies, having sent back all the silver she could command.

Germany, Holland, Sweden and Norway came into the market with their demonetized coin as sellers, instead of as before being purchasers. Our own mines were producing an enormous yield, and greatly exaggerated tales were circulated as to their future product. Our own Government followed in the blind track of the Europeans and demonetized silver. Instead of fostering our silver mining industry, it aided in its depression.

This combination of adverse causes, all acting in direct antagonism to the value of silver, produced its marked decline.

The reaction commenced when our Government made its partial restoration of silver to its true position as a standard or measure of value. The amount of silver coin accumulated in the Government vaults has somewhat of a tendency to restore silver to its former price. The return of confidence in commercial circles will call for its use in circulation. India will ere long commence a reabsorption. The financial storm has past. We have shown its causes. The avoidance of its recurrence will be to abstain from the violation of the natural law of finance, which has been exemplified by the experience of ages, that silver is a natural and necessary standard of value in connection with gold, and that to demonetize it, is to violate that natural law and to create an evil instead of producing a benefit.

An Iron Enterprise in Utah.—The Norway Iron and Manufacturing Company of Utah, having its principal office at Salt Lake City, has been incorporated "for the purpose of mining, smelting, milling and manufacturing metals of iron, gold and silver, and manufacturing pig iron, mineral paints and other articles of merchantable iron." The officers are John T. Lynch, President; Charles Popper, Vice-President; Frederick G. Lynberg, Treasurer; B. A. M. Froiseth, Secretary. These gentlemen, together with J. R. McBride, John Beers and Syvert Iverson, constitute the Board of Directors. The whole of the stock, $1,000,000, is paid up.

MECHANICAL PROGRESS.

Heating Steel in the Blacksmith's Fire.

In heating steel, two faults are especially to be guarded against. First, overheating; secondly, unequal heating of the parts to be operated on (whether by forging or tempering). Referring to the first, many blacksmiths do not recognize that steel is burned unless it falls to pieces under the hammer blows, whereas that condition is only an advanced stage of the condition designated as *burnt*. This is the secret of their partial failure, or, that is to say, of the inferiority of their work. Others recognize that from the time a piece of steel is *overheated*, to its arrival at the stage commonly recognized as *burnt*, a constant deterioration is taking place.

In the practice of some, this excessive heating may be carried to so small a degree as not to be discernible, except the tool be placed in the hands of an operator whose superior knowledge or skill enables him to put it to a maximum of duty, less skillful manipulators being satisfied with a less amount of duty.

But in the case of stone-cutting tools especially, and of iron-cutting tools when placed in the hands of very rapid and expert workmen, the least overheating of the tool will diminish its cutting value as well as its endurance. A piece of steel that is burnt sufficiently to break under the forging hammer, or to be as weak as cast iron, will show, on fracture, a coarse, sparkling, granulated structure, and this is the test by which working mechanics, generally, judge whether steel is burned or not. But it is totally inadequate as a test to determine whether the steel has not suffered to some extent from overheating. Indeed, although the grain becomes granulated and coarse in proportion as it is overheated, yet it may be so little overheated as to make no visible difference in the grain of the fracture, although very plainly perceptible in the working of the tool, if placed in the hands of a thoroughly good workman.

When the results attained are inferior, it is usual to place the blame on the steel, but in the case of well-known brands of steel, the fault lies, in ninety-nine cases in a hundred, in overheating, either for the forging or for the tempering.

In determining from the duty required of it, whether a tool comes up to the highest standard of excellence, the best practice must be taken as that standard. Thus, if it is a metal-cutting tool, as, say a lathe tool, let the depth of cut be that which will reduce, at one cut, say, a four-inch wrought-iron shaft down to 3¼ inches diameter, the lathe making, say, 16 revolutions, while the tool travels an inch, and making from 25 to 30 revolutions per minute. Under these conditions, which are vastly in excess of the duty usually assigned in books to lathe tools, the tool should carry the cut at least four feet along the shaft without requiring grinding.

If the tool is for stone work, let it be tested by the most expert and expeditious workman. These instructions are necessary because of the great difference in the quantity of the work turned out in the usual way and that turned out by very expert workmen.

At what particular degree of temperature steel begins to suffer from overheating cannot be defined, because it varies with the quality of the steel. The proper degree of heat sufficient to render the steel soft enough to forge properly and not deteriorate in the fire is usually given as a *cherry red*, but this is entirely too vague for successful manipulation, and, in practice, covers a wide range of temperature.

The formation of a scale is a much better test, for when the scales form and fall off of themselves, the steel, in fine grades of cast steel, is overheated, and has suffered to some extent, though the common grades of spring or machine steel may permit sufficient heat to have the scale fall off without the steel being worked. As a rule, the heat for tempering should be less than that for forging, and should not exceed a blood red. There are special kinds of steel, however, as, for example, chrome steel, which require peculiar heating, and in using them strict attention should be paid to all instructions given by the manufacturers.

Steel should be heated for forging as quickly as compatible with securing an even degree of heat all through the part to be forged, and heated as little as possible elsewhere. If this is not done the edges or thin parts become heated first, and the forging blows unduly stretch the hottest parts, while the cooler parts refuse to compress; hence a sort of tearing action takes place instead of the metal moving or stretching uniformly.

The steel should be turned over and over in the fire, and taken frequently from the fire, not only to guard against overheating, but because it will cool the edges and tend to keep the heat uniform.

The fire may be given a full blast until the steel begins to assume redness at the edges or in the thin parts, when the blast must be reduced. If the thin part is heating too rapidly it may be pushed through the fire into the cooler coals or taken out and cooled in the air or in water, but this latter should be avoided as much as possible.

When the steel is properly heated, it should be forged as quickly as possible. Every second of time is of the utmost importance.

There must be no hesitation or examining while the steel is red-hot, nor should it be hammered after it has lost its redness. There is, it is true, a common impression that by lightly hammering steel while black-hot it becomes impacted, but this only serves to make the steel more brittle, without increasing its hardness when hardened.—*Blacksmith and Wheelwright.*

BLOWERS VS. BELLOWS.—The important question as to whether a blower or a bellows furnishes the best power for forcing air into a blacksmith's fire is not yet settled; and probably never will be, to the satisfaction of everybody. Some blacksmiths advocate the one and some the other, each differing honestly. The American Institute of New York, recently instituted a contest or trial. Two pieces of iron, each 3¾ inches square and 7 inches in length—as nearly alike as possible. These blocks of iron were welded to rods some three feet long. Similar fires were arranged, one urged by the Centennial Hand Fan Blower, and the other by the Hurricane Bellows, each managed by their respective agents. The blocks were plunged into the fires simultaneously. The bellows were run at twenty-five up and down movements of the bellows per minute for 13½ minutes, when the operator said his block had reached a proper welding heat. Both irons were withdrawn at the same moment and it was decided by the judges that, although there was a perceptible difference in the degree of heat attained by each block of iron, still that difference appeared to be of only a trifling character; so that if the reputation of either method of propelling air was dependent upon this test, it would rest on a very slender foundation.

A NEW CASK AND BARREL HOOP.—Advertisements have recently appeared in American journals and a patent has recently been taken out in this country for a barrel hoop made of wire bent into corrugations, so that it has a serpentine form. It is claimed that this hoop, when driven upon a dry barrel or tub, will compress and hold the staves tightly together, like the ordinary hoop, but will have elasticity or spring enough to stretch when the staves expand by moisture, and return to its former position when the staves again contract on becoming dry; in this way the hoops will adapt themselves to the expansion and contraction of the barrel and the annoyance of loose or bursting hoops will be avoided. By forming the corrugations to rest flatwise against the staves, no obstruction is offered to rolling in case of barrels, while a much greater amount of friction surface is brought to bear upon the staves, increasing their holding power. The ends of the wire are secured together by twisting one end around the other. These hoops being made of wire, will withstand corrosion much better than flat hoops, as less metal comes in contact with the wood and less opportunity is afforded for the retention of moisture.

EDGE-LAID BELTS.—According to Leigh, a better method of producing a broad belt than the usual American double leather belting sewed together—a method by which the article can be made with the greatest ease, of any thickness or width, perfectly equal in texture throughout, and alike on both sides—consists in cutting up the hides into strips the width of the intended thickness of the belt, and setting them on edge, these strips to have holes punched in them about one-eighth of an inch in diameter and one inch apart; nails, made of round wire, clinched up at one end for a head and flattened at the other, are used for fastening the leather strips together. Each nail is in this case half the width of the intended belt, and after the strips are all built upon the nails, the ends of the latter are turned down and driven into the leather, thus making a firm strap, without any kind of cement, splicing or similar treatment. When a strap made in accordance with this plan requires to be tightened, it is only necessary to take it asunder at the step lines of the splice, cut off from each end of the strap what is required, and piece up again with wire nails or laces, going entirely through the strap.

FLEXIBLE LINING FOR KEROSENE LAMPS.—An ingenious invention has recently been introduced in Maryland to insure safety in the use of kerosene lamps. It consists of a lining made of flexible material, which prevents the lamp becoming foul by the expansion of the material of the lamp, permitting oil to exude and soil the hands, or whatever it may touch. A broken lamp becomes harmless, as there is neither gas from the oil nor oil itself to spread destruction to everything it comes in contact with. Careless handling will not bring the oil in contact with a hot lamp. The lining is a natural receptacle for fluids, a non-conductor of heat, and is improved in several essentials by being filled with oil. It is strong enough to resist rupture from much rougher handling than can be expected from an article designed for this purpose. No change is necessary in lamps now in use. The attachment is made to fit any kerosene lamp. An accommodation coupling, or joint, enables any one to change their lamp from a foul and dangerous light to one perfectly safe, clean and harmless. This lining is probably made of glue and glycerine, a mixture that always remains flexible, and is perfectly oil-proof.

WOOD-CENTERED car wheels, which are used in very large numbers for the passenger cars of English and Continental railways, have been found unequal to the duty enforced upon them by the higher strains due to the use of continuous brakes. Mr. Cleminson, an English engineer, has sought to render them fit for service under existing circumstances by changing both the construction of the nave and the bars. The latter is now made with a number of arms extending to within a short distance of the tire, which do not prevent a close fitting of the wooden segments. He has also improved the ordinary method of tire fastening by having the tire formed with a groove for the retaining ring. The main advantages claimed for wooden-centered wheels are a decreased wear of axle and tire, claims which seem to be borne out by comparative experiments made in French and German woods.

SCIENTIFIC PROGRESS.

Scandium.

Concerning the new element, scandium, of Nilson, M. Cleve has presented a more detailed account before the French Academy, and confirms to have found this element in the *gadolinite* and *yttrotitanite* of Norway in minute quantities. It forms but one oxide—Sc_2O_3. Its atomic weight is 45.12. The oxide is a perfectly white, infusible powder, resembling magnesia. It is more soluble than alumina in acids, yet it is only attacked with difficulty.

The specific gravity of the oxide is approximately 3.8. The hydrate is a white, bulky precipitate, resembling alumina, and is insoluble in excess of ammonia or of caustic potassa. The salts are colorless or white. They have a harsh, astringent taste, different from the sugary flavor of the other yttria earths.

The special interest surrounding the discovery of scandium, M. Cleve further states, is the fact that its existence had been predicted by Mendeleef in his remarkable memoir on the law of periodicity. In this he indicated the existence of a metal, which he named *ekabor*, whose characters, as given below, in brief, agree very closely with those observed of scandium, namely:

MENDELEEF'S PREDICTED CHARACTERS OF EKABOR.	OBSERVED CHARACTERS OF SCANDIUM.
Atomic weight, 44.	Atomic weight, 45.12.
Ekabor should have but one stable oxide Eb_2O_3; more energetic than alumina, but less basic than magnesia.	Only one oxide, Sc_2O_3; much more energetic than alumina, and feebler than magnesia.
A great resemblance between yttria and oxide of ekabor; their separation difficult, and only effected by differences of solubility, etc.	Scandium is less basic than yttria, and their separation depends on the different stability of their nitrates when heated.
With potassium sulphate forms double salt, having the composition of alum, but scarcely isomorphous with that salt.	Scandium and ammonium double salt is anhydrous, but has otherwise the composition of alum.
Few of the salts of ekabor will crystallize well.	The sulphate does not form distinct crystals.
Water will decompose the anhydrous chloride, with liberation of chlorhydric acid.	Water decomposes the chloride and evolves chlorhydric acid when heated.
The oxide will be infusible and with difficulty soluble in acid.	Ignited oxide is infusible, and dissolves with difficulty in acids.
Specific gravity of the oxide will be about 3.5.	Specific gravity of the oxide of scandium is 3.8.

The analogies existing between the predicted and observed characters of the hypothetical ekabor and of scandium are sufficiently remarkable to give another probable case of verification of Mendeleef's hypothesis, to which the attention of chemists was specially attracted by the discovery of gallium, where the predicted and ascertained characters were almost identical.

Mr. Crookes on Radiant Matter.

A few weeks since Mr. William Crookes, F. R. S., gave at the London Institution an experimental demonstration of recent researches on radiant matter. He observed that modern research during the last sixty years had greatly enlarged and modified our views on the constitution of gases, which were now believed to be composed of small particles or molecules that were constantly moving in every direction with velocities of all conceivable magnitudes. As these molecules were exceedingly numerous, it followed that no molecule could move far in any direction without coming in contact with some other molecule; but if we exhausted the air or gas contained in a closed vessel, the number of molecules became diminished, and the distance through which any of them could move without coming in contact with another was increased, the length of the mean free path being inversely proportional to the number of molecules present. The further this process was carried, the longer became the average distance a molecule could travel before entering into collision; or, in other words, the longer its mean free path, the more the physical properties of the gas or air were modified. Thus, at a certain point the phenomena of the radiometer became possible, and on pushing the rarefaction still further—*i. e.*, decreasing the number of molecules in a given space and lengthening their mean free path—the experimental results were obtainable, to which Mr. Crookes called the attention of his audience, and which were fully explained in a lecture delivered by him to the British Association at Sheffield in August last.

So distinct, be remarked, were those phenomena from anything which occurred in air or gas at ordinary tension, that we were led to assume that we were here brought face to face with matter in a fourth state or condition—a condition as far removed from the state of gas as gas was from a liquid. In some of its properties radiant matter was as material as wood or tin, while in other properties it almost assumed the character of radiant energy. We had actually touched the borderland where matter and force seem to merge into each other—the shadowy realm between known and unknown, which for him had always had peculiar temptations. He ventured to think that the greatest scientific problems of the future would find their solution in this borderland, and even beyond; there, it seemed to him, lay ultimate realities, subtle, far-reaching and wonderful.

Hydrogen as a Conductor of Heat.

A very interesting experiment is described as follows: "A very simple method of showing that hydrogen is a better conductor of heat than other gases, which is probably due to its metallic character, is described by Carl von Than. Two strong copper wires, several inches long, are held parallel to each other, but not in contact, by slipping over them two short pieces of glass tube, one an inch from the end, the other in the middle, and filling the tubes with plaster of Paris. The short ends of the wire are bent twice at right angles, so as to be an inch apart at the ends, and are connected by a very fine platinum wire. The wires are kept in a vertical position by clamping the second tube to a retort-holder or other support. The longer ends of the wires are bent apart and attached to the poles of a battery of three or four cells. The wires being insulated from each other, the current passes through the fine platinum wire, heating it red-hot. If a bell-jar of hydrogen be held over it, the wire ceases to glow, because heat is conducted so rapidly away. On bringing it into the air again it begins to glow."

In connection with this we remark, that experiments showing that a platinum wire made red-hot in the air by an electric current, will cool down when placed in an atmosphere of hydrogen, is a very old one; second, that the method above described to make the experiment is objectionable, for the reason that when a bell-jar of hydrogen is brought over the wire, the latter comes first in contact with the mixture of air and hydrogen, always present at the lower edge of an open bell-jar filled with hydrogen, forming an explosive mixture which the red-hot platinum wire may ignite, and soon burns up the hydrogen in the jar, bringing the experiment to a premature end.

A better way, and one that we always used when making this experiment before our classes in physics (some 20 years ago), was to take a wide glass tube, open at both ends, in which were inserted corks, each perforated with two holes, one for the conducting copper wire and one for a short glass tube, for the inlet and outlet of gases; the conducting copper wires were connected interiorly by a spiral of platinum wire, and one of the glass tubes exteriorly attached to a rubber hose, for the supply of gas. When the platinum spiral is made red-hot by the electric current, and hydrogen is introduced through the tube, the red-hot wire may ignite the mixture of hydrogen and air and blow out the corks, therefore we always first introduced carbon-dioxid (carbonic acid) gas, so as to displace the air with its oxygen; when the tube was filled with this gas and the spiral in full glow, the hydrogen was let in, the heat diminished, and the spiral lost its glowing appearance. By the re-admission of the carbon-dioxid it became glowing again.

The experiment may be varied and made more striking by passing through one of the corks two glass tubes, one for hydrogen and one for carbon-dioxid, when the platinum spiral may be made hot and cold in succession by admitting carbonic acid or hydrogen gas alternately.—*Manufacturer and Builder.*

EXPLOSION OF A DIAMOND.—At a recent meeting of the Academy of Natural Sciences of Philadelphia, Prof. Leidy exhibited a black agate sleeve button, which had set in it centrally, raised in a gold setting, a rose diamond, about 7 mm. broad. It had been submitted to him by Mr. Kretzmar, a jeweler, who informed him that the person who wore it was recently leaning with his head upon his hand on a window ledge in the sun, when the diamond exploded audibly, and with sufficient force to drive a fragment into his hand and another into his forehead. On examining the diamond, the fractured surface, following a clearage plane, exhibited apparently the remains of a thin cavity such as is sometimes to be seen in quartz crystals. The fracture also exposed a conspicuous particle of coal. Prof. Leidy thought that the explosion had been due to the sudden expansion of some volatile liquid contained in the cavity, as frequently occurs in cavities in many minerals. Mr. Goldsmith thought it possible that the liquid was carbonic acid, as he was impressed with the idea that diamonds originated from this material in the liquid condition.

A CURIOUS ACOUSTICAL ILLUSION.—M. Plumaudon, of the Puy de Dome observatory, has pointed out a curious acoustical illusion, which some of those who use a pair of telephones in receiving may have observed. With a single telephone held, say, to the right ear, the transmitted voice appears to come from a distance to the right; while with a telephone held to the left ear, it seems to arise from the left of the listener. With a telephone to each ear, if one ear be less sensitive than the other, or if the telephone be held farthest from that ear, the voice shifts to the side of the other ear; and if both ears bear alike and both instruments are equally near their respective ears, the voice apparently proceeds from in front of the observer.

Mining Share Market.

Operations have been light with modcrate fluctnations during the week, the most prominent being in Belcher; the statement of a strike not being powerful enough to cause more than a spurt, which is not yet looked upon as indicative of any strong action. All attempts to render the market buoyant have so far signally failed. The general business depression which, instead of subsiding, is evidently increasing, has a marked effect on the dullness of stock operations.

The Butte Creek Hydraulic M. Co. have rescinded the assessment, No. 4, of 15 cents per share, which was to have been payable February 13th.

On the Comstock, on the 2400 level of the Union, the finding of promising vein matter with low-grade ore, when east country rock or barren vein matter was looked for, was an agreeable surprise. The indications south and toward the Mexican line on this level are also an item of interest. The Gold Hill *News* says: The problem of mining at greater depths than have ever been reached in America bids fair to be practically and profitably solved in the near future hy the Yellow Jacket, Crown Point and Belcher. At present it can only he said that the prospect in these mines is good. It is known that helow the 2800 level of the Yellow Jacket there is pay ore, hut the amount and the characteristics of the formation are unknown. It is helieved that the formation continues through Crown Point. Belcher has demonstrated the existence of her vein as a well-defined formation hearing live and promising quartz as far down as the 3000 level; and on the 2760 level has fonnd hunches and streaks of pay ore, hut not in stoping quantities. The ore has not yet heen traced to any well-defined or continuous body; nor is it yet known whether it will make or give out. The promise of the future is hased mainly upon the fact that ore has been found; and that it will make and not give out is indicated hy the further fact that the ledge is some 40 feet nearer the incline on the 3000 level than on the 2760, showing it to he taking a steeper pitch. But if ore is there it will take six months yet to open it up. Overman is getting very promising rock in her crosscut east on the 1900 level, corresponding with the 2160 level of Belcher. Alta and Justice are showing up some good prospects to say the least, and these continue into the Silver Hill.

Bullion Shipments.

Since our last issue, we have noticed the following hullion shipments :

Eureka Con., Jan. 7th, 32,920 lbs.; Jan. 8th, 33,890 lbs.; Jan. 10th, 29,305 lbs.; Belmont, Dec. 29th, $3,317.25; Jan. 2d, $3,435.72; Bartell M. Co., Dec. 28th, $1,448.92; Paradise M. Co., Jan. 9th, $3,238.45; Jan. 14th, $4,942.85; Richmond, Jan. 10th, $1,743.04; Wells, Fargo & Co. at Eureka, Jan. 10th, $1,500; Ophir, Jan. 7th, $20,772.06; Grotefend, Hull & Co. Jan. 10th, 23¾ lbs. retorted gold; North Bloomfield in Dec. $29,955.00; Endowment, Jan. 3rd, $2,540.00; Argenta, Jan. 12th, $7,700.00; Northern Belle, Jan. 7th, $6,502.56; total in December, $92,000 in hullion; Alexander M. Co. since October last, over $100,000; Stonewall Mill & M. Co. (Arizona) in Dec., $15,099.98; Silver Reef (Utah), in 1879, $1,115,667.18; and the total for three years past, $2,559,779.36.

Mining Summary.

The following is mostly condensed from journals published in the futerior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

AMADOR CON.—*Dispatch*, Jan. 10: A report is current on the streets this morning that a fresh body of good rock has been found in this mine. Its extent or richness is not yet known.

ZELLE.—*Ledger*, Jan. 10: At the Zello mine, satisfactory progress is being made with fitting the machinery in the mill. It will be in running order in March.

GRASS VALLEY GRAVEL.—The Grass Valley gravel claims, near Volcano, are not fairly started yet, the late severe cold having interfered with the water supply.

BUTTE.

ARMSTRONG.—*Mercury*, Jan. 0: A six-stamp quartz mill is in operation, having started up Monday. Eight tons were crushed the first day. The greater portion was not considered as pay rock, yet it yielded to the satisfaction of the proprietors and far in excess of their anticipations.

CALAVERAS.

GWIN.—*Citizen*, Jan. 10: Work in the lower levels has been suspended for the present, owing to too much water. Work in the 500 level is still being pushed forward. At present only 16 stamps are being run.

MINE SOLD.—The sale of the Bonanza mine, near Copperopolis, to Sidney M. Brown, for $5,000, has created no little excitement in the neighborhood of Black creek and Christian gulch, near Copperopolis. Quite a number of parties have taken up claims on the lead of the Bonanza.

MINING SPECKS.—*Chronicle*, Jan. 10: A new flume is being put in at the Maison de Sante. Several loads of lumber designed to be used for that purpose passed through town during the week. Operations are not suspended while the improvement is being made. A partial clean-up was made at the Bonanza, the gold being emptied out of but a few of the boxes. We learn that the boxes cleaned were in such a plethoric condition as to indicate that when a *bona fide* clean-up is made it will throw all previous yields in this vicinity into a total eclipse. At the Eureka hydraulic work is being urged as hard as it can be driven. No water is brought through the new ditch, as it is frozen at the head. A few days of warm weather would give double the quantity of water now used. There is no cessation of operations at the Duryea hydraulic. An immense amount of gravel is daily put through the flume. An extensive cave occurred in the Green Mountain tunnel claim, a short time since. The debris has all been removed. In the Mammoth hydraulic work is prosecuted at the upper or north end of the claim. Piping is conducted in the vicinity of the Lamphear quartz mine and mill with every prospect of resulting favorably to the proprietors. Work continues in the great tunnel enterprise of the Happy Valley Blue Gravel and Hydraulic Mining Co. The tunnel has reached a length of about 300 ft, and is pushed ahead as fast as the hardness of the rock will permit. The company has not yet resumed hydraulic operations. At the Safe Deposit, Rough Diamond and other claims, operations are prosecuted energetically. Work has been resumed at the Champion mine, West Point, things having thawed out sufficiently to permit the resumption of operations. We learn that good rock has been struck in the upper levels of the Gwin mine and also in the Alexander shaft.

MARIPOSA.

ITEMS.—*Gazette*, Jan. 10: Peter Longhurst has sold a quartz mine for $2,500 to some parties in Oakland. The mine is two miles above Bull creek. The Banderita mill commences grinding its own rock this week. The owners have concluded a contract for grinding rock which was on hand at time of sale. The company has 100 tons of ore out ready for crushing. This is a ten-stamp mill run by water power. The contractors for running a tunnel 200 ft on the vein of the Austin mine, near Bower cave, have completed 125 ft, and the rock taken out looks exceedingly well. The Virginia mine and mill is ready to start. Much is depending upon the result of this mine, which, if it yields as well as is anticipated, will give an impetus to mining interests in that section. Martin Flanagan has lately struck good ore in his mine.

MONO.

SPAULDING MILL.—Bodie *Chronicle*, Jan. 3: The Spaulding mill is making good headway toward completion. The machinery is on the ground and being placed in position. The eight pans and four settlers are in place, and the engine also. The engine, a 90-horse power, is from the Fulton Foundry, San Francisco. The boiler, already set, is of steel, 16 ft long and 54 inches in diameter. The battery-room is 20x40 ft, and the pan-room 48x63 ft. The tank-room is 32x36, and the boiler and engine-room 23x43, with a wing, 10x23 ft. The retort house is south of and detached from the main works, and is 10x20 ft. When completed the Spaulding will be one of the best mills of its size in the State.

NOONDAY.—The drifts and stopes are driven rapidly. Ore sent to the mill assays well. Pumps are working six hours daily. A new cage has been put in the shaft in place of the skip. The mill is working to its full capacity.

JUPITER.—The cutting out of tank stations is the only work going on underground, preparatory to putting down new pumps. A boiler-house, 18x38, is being erected for a double set of boilers for the new pumping machinery. The boilers are 16 ft long, with a diameter of 48 inches.

BOOKER.—Crosscutting at the 400 and 480 levels; that at the 400 is in 70 ft; the 480 in 25 ft. The rock in the crosscut at the 400 level is becoming iron-stained, promising a vein approaching. The tank station at the 480 level has been cut out and plunger No. 2 will be put in on Monday. The water continues strong, but the pumps have no trouble in handling it.

ORIGINAL SUMMIT.—A small prospecting shaft is being sunk on the vein, preparatory to selecting a place for the commencement of a working shaft. The shaft is down 54 ft, and the vein is looking well.

MAYBELLE.—Still sinking the winze on the vein. Down 54 ft, and vein looks well.

MONO.—The heavy body of water struck last week has been controlled, and sinking resumed. The shaft is down 520 ft. The pumps are working well.

SOUTH BULWER.—*Free Press:* Sinking of the shaft now down 400 ft is resumed. Two Cope & Maxwell steam plunger pumps have been put in, one at the 300 level, and one near the bottom. There is no water in the bottom of the shaft; it is thought that it is drained by the Standard pump. As soon as water may be struck, the company are in a position to handle it. A winze is being sunk on the ledge from the 300 level, which is now down 78 ft. The ledge in the bottom is four ft wide, of good ore. A new boiler has been put in, and the hoisting works enlarged, their present dimensions being 30x30 ft. Wood and supplies have been laid in for the winter.

SOUTH NOONDAY.—The shaft, a double-compartment, cribbed and timbered, is down 122 ft. A ledge four ft wide was cut 70 ft from the surface, its strike being north and south, and its pitch east. The ledge was in the shaft for about 20 ft, and passed out to the east. A level will be run at a depth of 150 ft, and the shaft will be continued down. A substantial building has been erected over the shaft, 25x50 ft.

QUEEN BEE.—Crosscutting east on the 400 level is in 80 ft. Numerous strata of good quartz have been passed through, and it is believed the ledge will be cut in a few days.

BELVIDERE.—The new shaft has reached a depth of 400 ft, and a station at that level is being opened. The ledge is from six to ten ft to the east, and it will be cut in a short time in the east crosscut; as soon after as practicable, north and south drift will he started on the ledge, continuing the east crosscut through the favorable ground developed in the 200 level.

STANDARD.—The north drift, 585 level, is in 608 ft. The ledge is four ft wide. The south drift is in 280 ft. The ledge in this drift is three ft wide and continues to look well. The east crosscut, 500 level, is in 130 ft. The south drift from the west crosscut, 300 level incline, is in 115 ft. The ledge in this drift is two and a half ft wide. The east crosscut, 300 level incline, is in 94 ft. Rock in the face is very hard. In the 700 level, on the east side, the rock is very hard, but the west crosscut is in good running ground. There has been an increase in the flow of water. Sinking the shaft, which is 40 ft below the 700 level, has been resumed. The stopes throughout the mine are looking well. In the north drift, 385 level (vertical shaft) they are stoping from a ledge from 5 to 20 ft wide of good milling ore. On the 550 level, south drift, the ledge in the stope is eight ft wide of good ore.

WEST STANDARD.—This property continues to yield high-grade ore.

DOUBLE STANDARD.—The east crosscut from the bottom of the winze is in 77 ft. The north drift from the east crosscut, 200 level, is in 48 ft. The south drift, same level, is in 52 ft.

DUDLEY.—On the 500 level the main west crosscut is in 117 ft, with some change of ground for the better, which is much softer, and is working well.

TIOGA.—*News:* Shaft down 735 ft, and the vein in the shaft continues to improve; have cut several strata of rich ore, carrying free gold in large quantities.

SYNDICATE.—The drift is now in 644 ft, the face in hard ground. The east crosscut on the 620 level has advanced in vein formation and the indications favorable for soon cutting the ledge.

RALSTON.—The upraise from the 520 level, to connect with the 320 level on vein No. 3, is now up 57 ft, the whole face being in good milling ore.

ORO.—The west crosscut, 230 level, is in porphyry; have cut a well-defined ledge, 16 ft in width of low grade. The east crosscut, same level, is in favorable ground; have cut numerous strata and bunches of ore. The water is lessening, and sinking will be resumed as soon as it is drained.

MARYLAND CON.—The whole bottom of main shaft is in vein matter, carrying seams of rich quartz and clay. The stopes on the 258 level are yielding good milling ore. The ore continues good in the drift on this level. The 500 level will be reached by the last of the month, at which point a station will be opened and crosscuts for the company's three ledges started. Rapid progress is being made in advancing the work. The machinery works smoothly.

SUMMIT.—The north drift, 500 level, is in from the incline 25 ft. The ledge is three ft wide. The south drift is in 27 ft. The ledge here is two ft wide.

NEVADA.

DAVENPORT.—*Herald*, Jan. 8: Nine tons of the rock were crushed during the cold snap, when it was impossible to save all the gold. The result was a 20-ounce bar, which gives a yield of $30 per ton.

PLANET.—*Union*, Jan. 10: A washing of 15 carloads of gravel, without using quicksilver, yielded $10 in fine gold. The gravel was taken out of the incline drift being sunk for the bottom of the channel, where the gravel and gold is expected to be found coarser.

SHAMROCK.—The shaft is down 180 ft, and rock is being breasted out on the ledge, which is 18 to 20 inches in width. About 60 loads of rock are on the dump. No crushings have been made from the mine. The company contemplate fitting up the Perrin mill to crush their rock.

MAMMOTH BAR.—The shaft has been completed and drifting for gravel commenced.

GODFREY.—*Foothill Tidings*, Jan. 10: Their mill is ready to run, and they are taking out fine pay gravel and cement from the new tunnel. The Godfrey mill obtained its supply of water and began dropping its stamps on good pay gravel cement on Wednesday, and all is working well. The present way of working this mine over that through the shaft on Alta Hill makes a direct saving of $20 a day, and indirectly, year in and year out, quite a sum in addition.

YUBA QUARTZ.—The pay chute recently found in the main drift continues to show gold and sulphurets freely, and has widened to six ft.

IDAHO.—*Transcript*, Jan. 11: A gentleman who visited the Idaho mine yesterday informs us that 1,200 ft east of the main incline, 1000 level, the compact porphyry has again been encountered in the footwall. Invariably in this and the Eureka mines such an indication has been associated with heavy ore bodies. Eight hundred ft from the incline in the 1100 level the vein is six ft thick. The bottom of the main incline is at a depth of 1,200 ft, showing steady improvement. There is much dead work to be done before the mine will resume its former condition.

SHASTA.

MINING JOTTINGS.—*Courier*, Jan. 10: Our miners are all busy taking out the precious metal. Grotefend, Hull & Co.'s ledge at Mad Ox has 400 tons of ore on the dump, and the company continues to extract ore. Dr. E. L. Reese, of the Afterthought, is running off large quantities of ground, and is much encouraged at the way the mine prospects. The Impier company are at work sinking on their ledge, which looks well and widens as they progress. A. Potter, owner of the mill near Spring creek, is working his mill with rock from his various ledges, and is satisfied with the result. The Chenoweth ledge, near Middletown, is paying well, their only difficulty being the want of water on account of a break in the Clear Creek ditch. At Whiskytown there are various mines paying well, and the recent development in quartz near Deadwood has made French Gulch a prosperous town once more. The following named owners of mines were visited last week: Frick & Davis mine; H. E. Willey, Sebastion; Fred Diner, Henry Dore, McConnell. The above mines are near Deadwood, and the owners are clearing big pay from them. The Shafter quartz ledge is on French Gulch and Deadwood, from which he clears about $1,500 per week. The ledge of Frank Bros. is five miles west of French Gulch. They have cleared $3,500 in three clean-ups, and are about to make another one. The mines of George Kloin, near here, are said to be of the best in the district. At and near French Gulch there are many placer mines, and a good many smaller quartz claims, all paying well.

NEVADA.

WASHOE DISTRICT.

UNION CON.—Gold Hill *News*, Jan. 14: The east drift on the 2400 level is in from the shaft 188 ft. On the 2300 level the south drift toward the joint Mexican winze is in 460 ft.

OPHIR.—Preparatious for extending the pumps to the 2500 level and the construction of chutes at that point are going on. The north drift, 2500 level, is in fine-looking vein material carrying low-grade quartz; total length, 105 ft. The south drift, 2300 level, has reached the California line. The joint Mexican crosscut on this level is in soft vein porphyry, which requires close timbering; total length, 288 ft. The workings north on the Hardy vein, 2100 level, continue in heavy vein matter carrying quartz and clay; total length of drift from crosscut No. 1, 328 ft.

CALIFORNIA.—There are at the office about $52,000 in bullion, which will be shipped Saturday evening. Repairs on the 850 level have been so far completed as to admit of the resumption of work in that part of the mine and the north drift is being continued. The incline raise from the 1750 level for the 1650 is up 112 ft ou the slope. Connection will be made the last of this week or the forepart of next. The north drift on the 2250 level is in vein matter carrying low-grade quartz; total length, 250 ft. The Ophir south drift, 2300 level, is being continued on to connect with the C & C shaft at the 2450 station, and the shaft is to he sunk to that depth.

BELCHER.—The workings both north and south from the crosscut east, on the 2760 level, have been suspended to timber up. These workings have been pushed along the streak of ore about 35 ft in all, of which some seven ft are north of the crosscut. The streak of ore has been found to extend about two ft up from the hottom of these workings, so that the prospects lie helow the 2760 level. On the 3000 level the main east drift is in the vein, which contains bright, lively quartz. The south drift to get under the prospects on the 2760 level is still skirting the vein.

ALTA.—The north drift on the 1950 level is in 90 ft in quartz which gives low assays. The south drift, same level, is in the same distance in very much the same character of rock. The Lady Washington drift, on the 1550 level, will reach the north line of that mine to-day. The next movement will be to send crosscuts into the ledge in two or three places.

SAVAGE.—After the completion of the station at the 2400 level of the C. N. S. shaft, the work was turned over to the said shaft to be run. The incline has been cleaned out and repaired a distance of 125 ft on the slope. Connection with the Hale & Norcross on the 10th level is still being repaired.

CON. VIRGINIA.—There are on hand and ready to be shipped Saturday evening over $50,000 in bullion. The main crosscut west, 850 level, is ready for further work. The stopes on the 1550 and 1750 levels continue to yield ore.

SIERRA NEVADA.—The work of timbering the west drift, 2300 level, west of the incline, has been completed, as have also the chute on this level. The north drift, 2300 level, is passing through soft vein material. The north drift on the 2200 level is in a favorable vein formation; total length, 330 ft.

JULIA CON.—Work has been resumed in the southeast crosscut on the 2000 level. The winze from the 1800 level is going down and cutting a fine quartz formation. The water in the mine is handled by the pumps, but they are run nearly to their full capacity.

GOULD & CURRY.—The joint east crosscut on the 1700 level is 1,575 ft from the main north lateral drift and is still in dry ground. This crosscut is nearing the perpendicular of the new G. & C. and B. & C. shaft, its objective point.

MEXICAN.—The north drift on the 2300 level is now in 370 ft, the face in low-grade quartz.

CHOLLAR.—The drift on the 2100 level from the shaft is in 475 ft, and will reach a point from which the main lateral drift south, through Chollar into Potosi ground, will be started.

BELMONT DISTRICT.

BELMONT.—*Courier*, Jan. 3: The mine never looked better. In the north end for a distance of 300 ft there is a stope of low-grade ore that will average from $15 to $30 per ton, which is opened by two raises and two levels. This ore body is connected with the shaft from 300 to 500 levels, and there are thousands of tons of low-grade ore that can be taken out. On the 000 level a ledge has been cut 30 ft wide and carries from 8 to 12 ft of low-grade ore. This is the lowest point in the mine in which ore is found, and such a quantity of low-grade ore proves that the Belmont is a permanent mine. The stopes are producing their usual quantity of ore. The concentrator will start up on the 15th. Supt. Rogers feels sure that it will work satisfactorily, and then the thousands of tons of low-grade ore in the Belmont mine will be turned into silver bricks.

BRISTOL DISTRICT.

BRISTOL.—Pioche *Record*, Jan. 10: Work is being pushed ahead on the Gipsy and Cave mines, of the Bristol company. One of the trustees of the company is now in Chicago purchasing machinery for a 10-stamp mill, which will be shipped at once, a contract having been made with Warnock & Co. to deliver the same during the month of February. As soon as the result of the Raymond & Ely chloridizers is made known, if a success, the Bristol company will order the same.

HILLSIDE.—The Hillside furnace started up yesterday and is running well, with machinery in splendid working order, a large amount of ore on dump and from 35,000 to 40,000 bushels of coal on hand. The cupel furnaces are in good working order.

MEXPHIA.—A large body of high-grade ore has lately been uncovered in the 110 drift off the old shaft, which is improving as the work goes down. Good ore is being taken out from all parts of the mine, especially from the old workings on the first level.

LAURA G.—Work, which has been suspended upon the the Laura O. for some time, will be resumed this coming week. The lessees have let a contract to run a tunnel, tapping the main ledge at a depth of 110 ft.

EUREKA DISTRICT.

CENTRAL HILL.—*Sentinel*, Jan. 7: Some high-grade ore has recently been extracted. The mine is owned by M. H. Joseph and Mr. Peterson, both of whom are elated over their promising prospect.

CALIFORNIA.—*Sentinel*, Jan. 10: This mine, lying immediately south of the Conuolly, on the lead, is looking well. Competent miners regard it as one of the most valuable mines to the southward of Ruby hill. It is the property of Joe Mendes, Alex. McKenzie & Co., and is being worked with good results.

TYBO DISTRICT.

MORAY.—Tybo *Sun*, Jan. 10: The principal work now going on is sinking the main shaft and running a tunnel. In the shaft they are having some trouble with water, but the tunnel will drain the shaft and enable them to sink faster. The tunnel will tap the shaft at 400 ft.

TYBO.—The mill has been running steadily, but will shut down for a day or two, to make repairs. The output of bullion from here for the month of December was something over $10,000.

ARIZONA.

TRUE BLUE AND ORONELL.—Pima *Record*, Jan. 3: Thes two mines have been sold to New York and Boston parties for $25,000—20 days being allowed for payment.

TUCSON DISTRICT.—Capt. W. L. Campboll reports that many valuable claims are located in Tucson district, which is situated about 60 miles from Tucson and 10 miles south of Tubac, running along the Sonora line and taking in the west side of the Patagonia mountains.

ESPERANZA.—*Citizen*, Jan. 3: The Esperanza sale has gone through. The parties who were sent here to examine the mine, made such an examination as satisfied them that there was enough ore in sight to more than pay for the property if not another foot of sinking were done. Some $200,000 worth of ore, assaying over $100 a ton, was measured. Work will be pushed ahead. The chances for getting through the mundie are better.

MINING ITEMS.—*Arizonian*, Jan. 2: Mr. J. H. Kelley, who has followed placer mining on the Hassayampa for 10 consecutive years, informs us that about 20 men are now employed in sluicing on that stream, mostly at the mouth of Copper creek. They average from $2 to $6 per diem, and there is plenty of ground there for more miners. George Carr is at work on the old Jackson hydraulic claims, on Lynx creek, and is doing well. Mr. Smith is ground-sluicing in the same locality, with good results.

TOMBSTONE ITEMS.—*Nugget*, Jan. 8: The new working shaft at the Head Center, about half way between their prospect operations and the Contention hoisting works, is 115 ft deep, and the rich gold ore, which has always characterized that mine, has been found. Some silver specimens, taken out at a lesser depth, looked to us as though they might be equal to anything the district has ever known. Owl's Nest or Minerva, is now a bone of contention. Three different parties are working on the claim. It will result in a thorough test of the claim. Work of developing has been commenced on the Longfellow, Contact, Eagle, Iron Clad, Baker, Randolph and Junietta claims. Commenced on the 5th hauling ore to the mill from the Lucky Cuss mine.

MINING NOTES.—*Miner*, Jan. 10: Messrs. Everett and Waite have purchased an interest in the Cachise, Washington district, and are moving men and material to the ground, preparatory to sinking a 50-ft shaft. The Cachise is parallel with and adjoins the Pensacola on the west. Five miles from Harshaw, on the northwest slope of the Patagonia mountains, Mr. Crooker has found a well-defined carbonate ledge, going 200 ounces. Oeo. Atkinson has struck it rich west of the Blue Nose; fine body of galena and carbonate ore assaying $90.

COPPER MINES.—Mr. Holland, just in from the Huachucas, reports the discovery and location of an immense body

[CONTINUED ON PAGE 44.]

Governor Perkins' Inaugural Address.

As this is acknowledged to be a time of unusual moment in our public affairs, and as our industrialists should be fully informed concerning the position taken by the new administration, with regard to their interests, we quote from the inaugural address of Governor Perkins the following paragraphs, in which the material welfare of the State is discussed:

Agricultural and Mining Interests.

Of the largely diversified interests of California, agriculture and mining are the principal sources of our prosperity and wealth. All cereals and fruits here yield most abundant harvests. The soil responds to man's industry, and rewards his labors. Yet, ancient and honored as is agriculture, constant improvments are being made in its departments, and new discoveries augment the net gains. It is the duty of the State to foster the agricultural interests by providing for the dissemination of trustworthy information respecting her resources, the character and adaptation of her soils, so that the newcomer may enter upon his labors with an intelligent confidence in the result.

A progressive step has been taken during the past year at the University, in the establishment of a garden of economic plants, in which a large number of growths proposed for culture in this State are being tested.

Still the science of agriculture in our State is yet in its infancy. The peculiarity of our soils, seasons and climate, makes the ripe experience of other countries unavailable to us in our methods of agriculture. An unskillful and unscientific agriculture will impoverish our soil and eventually convert our fertile valleys into desolate wastes. The carefully collected experience of the older States, which constitute the literature of the science of agriculture, being unavailable to us, we are dependent upon self-instruction for what we now know or have yet to learn of the most scientific methods of field and orchard cultivation. The Bureau of Agriculture at the National Capital is a most valuable aid in the dissemination of intelligence on the subject of scientific agriculture, as that science may relate to the laws of production under the conditions existing in the great body of States in this Union. But the peculiarities of condition existing in this State call for the evolution of a special science of agriculture, and as a means to that end I most respectfully recommend that through our Congressional delegation in Washington, the Congress of the United States be memorialized to establish a branch of the National Bureau of Agriculture on the Pacific coast.

Further, and appropriately in this connection, your attention is respectfully directed to the wise encouragement heretofore given by this State in the way of promoting a higher agriculture by stimulating annual exhibitions of the highest results of industry. This encouragement should be continued under the guarded restrictions of the Constitution of our State.

Mining, for a long time the principal pursuit of our people, is still one of the most active and profitable industries. Its importance to the State and to the nation cannot be overestimated or gainsaid; and it is not without pride that we point to the fact that, since the discovery of gold here, California alone has produced over $350,000,000, more than the aggregate productions of all the rest of the United States. As results are the measure of success, these many millions prove the importance—State and national—of the mining industry, and ought to relieve it of its supposed speculative character. There is a broad and well-defined distinction between the legitimate California miner—the producer of these vast sums—and the stock speculator who deals in paper evidences of titles to supposed mining properties. While legitimate mining has accomplished so much for the State, it must be admitted that the State has not done all it ought to have done for mining. We provided for a State Geological Survey, which was barren of any useful results, and before its completion a School of Mines was founded at the University, the outfit of which has never been furnished, and its chair is vacant.

It is not due to the mining interest that the results of the geological survey already paid for, compiled and collected—such as are practical in their nature—be made public property, when no expense is entailed, except that of their publication? What has been done we should have the benefit of.

Debris.

In several sections of the the State a conflict has arisen between the mining and agricultural interests in relation to the debris washed down by the rivers. The best interests of the State require that this most important and most delicate question should be settled upon some broad and comprehensive basis. The report of the Board of Engineers, provided for by the last Legislature, will doubtless furnish you with information in this connection.

Irrigation.

The important subject of irrigation, with special reference to the San Joaquin valley, has been the topic of investigation by the State Engineer and his able corps, and it is expected that his report to the Legislature this session will present some data upon which may be based wise legislation.

Freights and Fares.

The progress made in the construction of railroads during the past half century, the convenient facilities they furnish for travel and for the rapid interchange of commodities, have brought their relations to the State into a prominence that cannot be ignored by those occupying, or who would occupy, official stations.

Transportation companies move the agricultural and manufactured productions of the world. Their growth has been so overshadowing that the earnest attention of the wisest statesmen of both hemispheres has been directed to the subject of governmental supervision. In some of the older States such supervision has been tried and abandoned. In others the experiment has met with approval, and has resulted in a better understanding between the public and the railway companies. In this State we have had two commissions created by statutory enactments and clothed with limited supervisory authority.

The railroad companies disputed the right of the State to interfere in their affairs, and this attitude undoubtedly tended to the adoption of the far-reaching provisions in the new Constitution intended to regulate and control transportation companies.

A commission authorized by that instrument has been chosen by the people. Its powers are almost unlimited, and partake of the legislative, executive and judicial. The wisdom of delegating such extraordinary powers to such limited numbers is not open to discussion or challenge in this place. The people, with whom the power rested, have so decreed, and it remains for their servants to obey. Yet I trust that the Transportation Commissioners will not consider me as exceeding official courtesy if I give expression to the hope that they will be able to effect a more harmonious relation between the transportation companies and the people whom they serve. Some of the constitutional provisions governing this subject are probably not self-executing, and will need legislation to give them the effect designed by their framers. I respectfully invite the attention of the Legislature to this subject, and recommend the passage of such laws as shall meet the requirements of the case.

Revenue and Taxation.

The highest prerogative of government, and one of the most difficult to deal with, is that of taxation. In his inaugural address in 1871, Governor Booth aptly said: "No scheme of taxation has ever been devised which was absolutely just; perhaps none can be." This condition must be accepted; but the nearest approach to equality of taxation that experience can suggest must be our aim.

The revenue laws of the State have been in great part abrogated, and much legislation on this subject is rendered necessary by the new Constitution. The taxation of mortgages, which is one of the new features to he dealt with, will not produce any additional revenue, and will only operate—for good or evil—between borrower and lender. It is required that the amount of the mortgage he deducted from the realty on which it is a lien, and the proceeding renders cumbersome and complicated the duties of both Assessor and Collector.

It is also required that all real and personal property, including credits, franchises, bonds and stocks, shall he taxed, and laws must he passed for the carrying out of this requirement. Not, however, in such manner as to result in double taxation, to which I am most emphatically and unalterably opposed. Debts due to A should be made an offset to a like amount of debts A might he owing to B, and the assessments made on the balance only. The stock of corporations is required to he taxed. If an attempt is made to tax the real and personal property, franchises, etc., of private persons and corporations, and another taxation of the stock and individual bonds, it would he double taxation, and, as such, oppressive and unjust. To prevent this, and at the same time to insure that all the property of any firm or corporation having a capital stock shall be properly taxed, would it not he the plan of wisdom to secure the assessment of all stock at its market value to the company issuing it, after deducting the value of all assessments on the real and personal property of such company as may have been otherwise made.

By this means many millions of dollars may be added to the taxable wealth of the State. The tax being paid hy the company, the distribution of the assessment among the stockholders would he equitable, while to attempt to assess the stock to individual holders would prove practically impossible, and result in much of it escaping taxation.

Under the present law improvements constructed on real estate which is itself exempt from taxation are not assessable. It seems only just that the code should he so amended that the improvements alone may he made liable for the amount of the tax.

The new Constitution makes provision for the assessment and collection of income taxes in such cases and amounts, and in such manner as shall he prescribed hy law; and while I am not prepared to recommend immediate legislation upon the subject, I am persuaded that a tax upon personal incomes exceeding, say, $5,000, properly and impartially executed, would be of most essential service in imposing the burden of taxation upon those most able to bear it, and compel them to aid in supporting the Government which makes possible the acquisition of wealth, and protects its possession, thus relieving the limited means of the less fortunate, and the small property of widows and orphans from unnecessary impositions. But for the constitutional inhibition against exemption of any property from taxation, I should have been happy to recommend a moderate exemption from taxation of the property of these certain classes of persons; but since that is impracticable, their burdens may be lightened hy a just and searching income tax.

Chinese Immigration.

At the last election, in accordance with the statute providing therefor, a vote of the people of this State was taken upon the question of Chinese immigration—"for" and "against" the policy of permitting it to continue unrestricted, as at present. Out of a total vote of 161,405, only 883 votes were "for" such immigration. The ballot was secret—there was no extraordinary excitement on the subject; the result should be accepted as a fair indication of the real opinion of our people on this important question. It ought to be accepted everywhere as conclusive evidence that there is practically no difference of opinion among the people of this State relative to the policy of prohibiting the further increase of the Chinese element of our population. The question has ceased to be a political issue with us. Men of all parties are in perfect accord that emigrants from China are a curse to this country, and that some adequate restriction upon their coming ought to be imposed without delay.

An experience of thirty years has convinced them that immigrants from China do not and cannot assimilate with our people. They come hither without families, with no accurate ideas of free government or of christian civilization; they retain their native dialects, their national prejudices, and even their race costumes. They take no interest in our political affairs, and manifest no desire to be identified permanently with the country, as do immigrants from other parts of the world. They are handicapped by labor contracts which reduce them to a condition worse than slavery, for the servitude cannot be abolished. Their contracts cannot be annuled by our laws, because they are founded upon the laws, customs and religious prejudices of China. The result is to renew in another form the "irrepressible" conflict between free and servile labor, which has already cost us one civil war. Hence the people of California say: Here is a new problem in American politics. Our republican government has extended its jurisdiction across the continent and stands face to face with the oldest civilization known to history. It confronts the most populous nation in the world—a country so populous that numbers equal to the entire population of the Union could be spared and their absence scarcely noticed. In all the Pacific States and Territories the population is less than one million and a half—utterly insignificant when compared to the 400,000,000 in China. It costs much less for the immigrant from that country to reach this State than it does for the immigrant from Europe, or even from the older States of the Union.

Already nearly one-third of the men among us who make their living hy their daily toil are Chinamen—Chinamen without families to support, while most of the white laborers have wives and children to provide for. In this country the family is the unit of society. It is the family that makes the home, and the homes of our people are the citadels of our liberty. It is there that respect for law and the love of freedom are fostered until they become so much a part of the nature of the child that when he reaches manhood he is a useful portion of the political fabric. The Chinese know nothing of this American home culture, and we believe they are incapable of comprehending it. Hence they can never become American citizens in the true sense of the word. Bound in servitude, they differ radically from the class of immigrants for whom our ancestors entertained so friendly a feeling, and whom we have always received with hearty welcome. A new evil arises, for which we must provide a new remedy; that remedy we believe is to restrict the immigration of that class of people; and it is for the Federal Government to apply it. The expression of opinion through the vote lately taken was intended for the purpose of influencing such action, and it is to he hoped that it may have that effect.

While we must look to the General Government for the complete redress of this evil, the people have attempted, in the New Constitution, to find some relief through the action of the State Government, by directing certain measures to be applied. The attention of the Legislature is therefore respectfully invited to this subject, with the assurance that whatever can be properly and legally done in this behalf by the State shall have my hearty co-operation.

Land Monopoly.

One great source of our success and prosperity as a nation is that, under a wise system, the public lands have been disposed of in small tracts to actual settlers. Attaching men to the soil hy ownership creates an independent and intelligent population. While there are large areas of dry and desert lands that cannot he cultivated without large expenditures for costly works of irrigation, and large areas of swamp lands unavailable for agriculture until vast sums are expended in their reclamation, yet, wherever hy legislation men have been enabled to monopolize and reduce to private ownership large tracts of farming land for purposes of speculation, it has been in opposition to the wise policy of the founders of the Republic, who sought to give every man wishing to cultivate the soil as much land as would support him and his family, and no more.

In the acquisition of California from Mexico we inherited the evils of a different system. Vast tracts, measured not by acres, but by leagues, of the best lands, had been granted to private individuals and secured to them by treaty. However much the public prosperity would be promoted by division and sale of these large tracts to actual settlers, I know of no mode by which they can be divided and sold without the consent of the owners.

The State could not exercise her right of eminent domain, and condemn them, for it would be an appropriation of private lands for private purposes; something unknown under our system of government. This evil must be left to time for its eradication. We can have no law of primogeniture and entail; therefore, the evil will not be perpetual. The fluctuation of business enterprises, the certainties of taxation, and the laws of inheritance will in a few years divide and subdivide these great possessions.

The new Constitution requires that cultivated and uncultivated land of the same quality and similarly situated, shall he assessed at the same value. This, with equal taxation prevailing to such an extent that the owner of his leagues of land shall be assessed the same value per acre as the owner of 100 acres, providing the land is of equal quality, and the few will soon realize the fact that it is not profitable to monopolize the lands of the country. As to the large bodies of public lands within our State still remaining the property of the United States and of the State, that can he cultivated without large expenditures for irrigation and reclamation, I am in favor of such disposition of them only as will provide for their conversion into homes of not exceeding 160 acres for actual residents thereon.

But while I consider the policy of taxing uncultivated lands equally with cultivated lands of the same quality to be not only a step in the right direction, but one of the most important reforms in the new Constitution, yet the carrying out of this important trust will devolve upon the Assessors of the different counties and the State Board of Equalization; and if they faithfully perform the duties assigned them there is no doubt in my mind that the immense tracts of uncultivated lands now held for speculative purposes will soon be a matter of history.

It is estimated by the United States Surveyor-General, that there is yet in this State about forty millions of acres of public lands unsurveyed. Our Senators and members of Congress should be requested to urge Congress to make the necessary appropriation to have these lands surveyed, and conveyed to actual settlers only, as it can but conduce to the encouragement of immigration to this State of intelligent, thrifty and sturdy farmers from other States and countries, to come and settle in a State which possesses such unbounded resources. I shall be pleased to give my hearty co-operation and concurrence to any legislation which favors a policy of conveying our public lands to actual settlers only, and the discouraging of holding large landed estates.

Harbor Commissioners.

The Board of State Harbor Commissioners reported to the late Legislature a bill which provided for a new water front for the city of San Francisco, and recommended that the lands reclaimed by their proposed plan, if adopted, should he sold.

The Legislature confirmed their suggestions, but wisely declined to authorize the sale of the reclaimed lands. The question now arises, what shall he done with them? Shall they he sold, or he held as the property of the State?

The port of San Francisco belongs to, and is of most vital importance to, the State of California; and her citizens are her agents in the domestic and foreign commerce of the State. The State has reserved ownership of the lands on the city front, and controls and directs their use for commercial purposes. Every facility that can he afforded to cheapen the cost of carrying on the exchange of products of the State for those of other countries needed to supply her wants, is of direct pecuniary advantage to every one of her citizens, however remote he may reside from this, her commercial seaport. A wise statesmanship will foresee and provide for her future commercial requirements, and make such provisions in advance as will create new sources of prosperity, or hasten and secure them to herself. Necessarily the surplus products of our State find their money value measured hy prices fixed in foreign ports, and under foreign competition; hence every dollar that can be saved in the cost of production and transportation (in facilities for handling, storage, wharf and other port charges), inures to the benefit of the State and its producers, and will go far to help them meet the competition in foreign markets. Every convenience that can he afforded to get our products into the ships, and also to the ships themselves (which are to carry them away or bring back their returns), is a profit which goes directly into the pockets of the producers.

So, also, if we furnish better and cheaper facilities to the trade of our neighboring nations in the Pacific, we shall induce the trade of these countries to pass through our port, to the direct and indirect advantage of our people. As commerce has created these new lands on the water front, they should not be sold hy the State to individuals, but be reserved and sacredly appropriated to commercial uses forever.

These lands are not needed for such purpose to any great extent, but as our State and cities grow, the purposes for which different portions of them will be most useful will develop gradually, and a continuance of the wise policy which has reserved them will assign to each portion its

proper share in serving the great commercial needs of the mstropolis of the Pacific coast.

Education.

The public system of education will demand at your hands much earnest and careful consideration. The framers of the Constitution of our State declared a general diffusion of knowledge and intelligence to be essential to the preservation of the rights and liberties of the people. Whatever power governs the schools, shapes the intelligence of the generation. The destinies of a republic rest upon an intelligent suffrage, and the intelligence of the suffrage depends mainly upon the public school system. The changes in the system made necessary by the new Constitution presents an opportunity of a general review of the existing system, and such wise reconstruction and improvement as experience may have suggested, or patient and earnest consideration may develop. A republican government will always be a perfect reflection of the true character of its people, and if we would attain that "righteousness which exalteth a natioo," and avoid that "sin which is a reproach to any people," we must become, in its best and truest sense, an educated people. Liberty will not decay so long as government is controlled and directed by virtuo and intelligenco, and in a State like ours, where the people are the source of governmental power, general education is the only means by which we may hope to transmit the free institutions under which we live in full vigor to succeeding generations. To neglect or abandon our system of public education is a surrender to the ignorance and vice which usurp the reins of government when virtue and general intelligence are weakened or decay. Educate our people, and the liberties we enjoy will remain unshaken by the assaults of insiduous usurpations and undiminished by the flight of time.

The State University is the crowning glory of our educational system. The new Constitution wisely provides for its continuation as a public trust. By the terms of that instrument its government is to be perpetually continued in the character proscribed by the Organic Act, passed March 23, 1868, and the several Acts amendatory thereof. It is now subject only to such legislative control as will insure compliance with the terms of its endowments. It is further provided that the funds derived from the sale of lands donated to the State by the Government of the United States shall be invested as directed by the Acts of Congress, and the interest accruing shall be devoted to the maintenance of a College of Agriculture, where such branches of learning as relate to scientific agriculture shall be taught. It will be the high privilege of this Legislature to devise the necessary details of legislation by which the object of the original grant or donation to this State shall be carried into execution, and I am happy to believe that this responsible duty will be esteemed a sacred privilege, and the obligations imposed will be discharged with that conscientiousness a true appreciation of the moral grandeur of the subject inspires.

Conclusion.

At the threshold of the administrative duties into which by these ceremonies I am being inducted, I am conscious of a most earnest desire to discharge them as in the high court of truth, honor or justice. To achieve the distinction of an honorable position in the State may be the goal of self-love and pride; to rise equal to the high prerogative by the conscientious discharge of its duty is the more worthy aspiration of ambition. For the brief term I shall enjoy the honors and bear the responsibilities of this exalted office, I trust that my every thought shall be directed to the welfare of the State, and my every effort devoted to the promotion of peace and prosperity, the establishment of good government and the advancement of Christian civilization.

The Indiana Mine.

The Inyo *Independent* furnishes the following description of the Indiana mine, which is situated about three miles west of Owens lake, in the Inyo mountains, at an elevation of 1,500 feet above the lake:

"The country lying to the east of Swansea is attracting considerable attention, and having in view its future importance, we devote some space to what appears at present to be the best developed and so far the most productive property.

"The central vein cuts through a long hill of solid and apparently primitive formation. Its course is north 10° west. On the west the country is quartzose and black slate; on the east the mineral zone is confined by lime, greenstone and slate strata. In the canyons, on either side, are shown small veins of argentiferous rock tending to a common center somewhere on the principal line of location. The Indiana was discovered some 18 months ago by James Hauger, and in April last purchased by Boley & Tuttle, who have since made the property pay its purchase money and all expenses. The vein is a small one, standing nearly vertical, of a width ranging from 4 to 18 inches, perfectly continuous and well-defined. The ore is of sulphide and gray carbonate, the first class carrying 800 ounces silver per ton, the second 400 and the third 100. A specimen on exhibition at the San Francisco office, which weighs 12 pounds shows horn silver and sulphides, and is estimated to contain $60. With a force of four men a tunnel has been run on the line of the vein 230 feet in length, attaining a depth of 115 feet. From this level two winzes have been sunk to a depth of 85 feet, and (at the time of our visit) 18 feet showing very rich ore in all and presumably a block of it 85x140 feet. On the dumps were four tons of second and six tons of third-class ore, the whole assaying from $210 to $380 per ton, which is now at the New Coso furnace in Darwin for reduction, where Mr. S. D. Woodhull, of the Independence assay office, has gone to deliver and sample the same. The extensions consist of claims of the legal length of 1,500 and comprise, 1st—the Virginia, adjoining which comes the Marx Stemler. Finding a vacancy here on the lode line, Capt. J. M. Keeler located and owns the Grand Center, comprising 1,320 linear feet. Next adjoining is a claim belonging to Thos. Moran, upon which he has run a tunnel 40 feet in length showing ore of the same rich class. The Flagstaff mine, the property of C. Meysan & Co., is the next location. This is developed so far by a shaft 110 feet in depth, and has upon the dump 15 tons of $300 ore. Ore sent to San Francisco from this mine has well repaid all the cost of extracting and shipment. A claim of Geo. Desalier, Stone & Co. comes next, followed as you ascend the slope by locations more or less opened, belonging to Jas. Hanger, J. H. Dodge and C. Meysan, and one called the North Discovery, owned by Col. Boley. For all this long line, comprising over 13,000 feet, the ledge is distinct and the ore assays hold the same high average. Certainly, 'there is something in it.'"

Useful Information.

The observation of the circulation of the blood in living creatures has always been regarded as the most interesting and instructive sight that the microscope could afford. The delicate membrane of the foot of the frog has hitherto afforded the microscopist the most convenient subject for this beautiful demonstration of Harvey's discovery. Perkinje's experiment, by which an observer is enabled to observe the circulation in his own retinal blood-vessels, has hitherto been the only method known of actually showing the circulation of the blood in the human subject. Dr. Huber, of Greifswald, it may interest our readers to know, has lately described a simple experiment by which it is possible for an observer to see the circulation of the blood in the blood-vessels of another person. Dr. Huber fixes the head of the subject to be examined in a frame not unlike that used by photographers, on which is fixed a holder for the microscope and lamp. He then draws down the lower lip of the subject upon the stage of the instrument with its delicate inner surface upward for inspection, throws a strong light on the same with a condenser, and focuses the microscope, provided with a low-power objective, down upon the delicate network of blood vessels, which can be seen there even with the naked eye. By this simple means the circulation can be observed with the greatest ease and perfection. The value of this novel and beautiful experiment in the study of the abnormal conditions of the blood, presented in various diseases, it is anticipated, will be very great, and important results are expected to flow from it. Huber distinguishes his new process by the terrific name of "cheiloangioscopy."

Incendiary Silks.—The danger of spontaneous combustion, to which weighted silks are liable, during transportation, has lately been forcibly demonstrated in the case of the steamship *Mosel*, which mysteriously took fire recently in mid-ocean. The fire was fortunately discovered and extinguished. On reaching her destination, a careful investigation afforded unmistakable evidence that the fire had originated spontaneously in certain silk goods that had formed part of her cargo. Samples of the silk, under the microscope, presented a remarkable appearance. The fibers ran very irregularly, and were partly covered with scales of a metallic luster, while on other fibers, heavy, sponge-like knots of a dark color were observed. A chemical examination revealed the following remarkable results: One hundred parts of the silk were composed of pure silk fiber, 21.34%; oxide of iron, 13.45%; moisture, 9.15%; fatty oils, 1.85%; organic dye-stuffs and coloring matters, 50.90%; mineral matters not determined, 3.30%. For each part of silk fiber, therefore, it was shown, 0.75 part of oxide of iron and 2.50 parts of coloring matters were used.

Hard versus Soft Water.—Dr. Tidy, an English chemist, gives, in the London *Medical Examiner*, the results of his observations on the use of hard water for culinary and domestic purposes: 1. Hard water is the best dietetically, because of the lime. 2. It makes better tea, although not so dark colored, owing to the fact that soft water dissolves the bitter extractive matters which color the tea, but ruins the aroma. 3. It relieves thirst, which soft water does not. 4. It does not dissolve lead or organic matter, which soft water does. 5. It is generally good colored, soft water being, as a rule, dark colored and unpleasant looking; hence, in places like Manchester, supplied with soft water, they always put it (in hotels) in dark bottles, to hide the color. A soft water, however, is a better detergent, and requires less soap. For a residential town a water which has over 10° of hardness would be best. For a manufacturing town a soft water would be the most advisable, for commercial considerations only.

For Cleaning Kid Gloves.—Among the many methods for cleaning kid gloves, the following may be given: Put them together with a sufficient quantity of pure benzine in a large stoppered vessel, and shake the whole occasionally with alternate rest. If on removing the gloves there remain any spots, rub them out with a soft cloth moistened with ether or benzole. Dry the gloves by exposure to the air, and then place smoothly between glass plates at the temperature of boiling water until the last traces of benzine are expelled. They may then be folded and pressed between paper with a warm iron. Another way is to use a strong solution of pure soap in hot milk beaten up with the yolk of one egg to a pint of the solution. Put the glove on the hand and rub it gently with the paste, to which a little ether may be added, then carefully lay by to dry. White gloves are not discolored by this treatment, and the leather will be made thereby clean and soft as when new.

Firearms frequently burst when the muzzle has been accidentally closed with earth, snow, etc. Prof. Forbes' explanation of this fact is very simple. If the charge moved slowly, a very slight pressure of the air in the barrel would be sufficient to clear the muzzle, but as the charge actually travels with a speed greater than the velocity of sound, the resistance offered by the obstacle becomes excessive and the gun bursts. It has been demonstrated mathematically that the pressure generated by a plug of the density of air is seven and half tons.

Composition for Pool Balls.—A good and inexpensive composition that would be hard enough for pool balls may be made as follows: Melt together over a gentle fire in an iron pot, pitch 1 part, gutta-percha 2 parts, orange shellac 5 parts; add to this 6 parts of white lead (lead carbonate) in impalpable powder, and stir until a perfectly homogeneous mixture is obtained, then cast and turn out. Color with the aniline dyes mixed with dilute alcoholic solution of bloached shellac.

Cement for Leather Belting.—One who has tried everything says that after an experience of 15 years he has found nothing to equal the following: Common glue and isinglass, equal parts, soaked for 10 hours in just enough water to cover them. Bring gradually to a boiling heat and add pure tannin until the whole becomes ropy or appears like the white of eggs. Buff off the surfaces to be joined, apply this cement warm, and clamp firmly.—*Amateur's Handbook.*

A dry coating for basement walls may be made as follows: Take 50 pounds of pitch, 30 pounds of rosin, 6 pounds of English red, and 12 pounds of brickdust. Boil these ingredients, mix them, and stir them thoroughly, then add about one-fourth the volume of oil of turpentine, or enough to make it flow easily, so that a thin coating may be laid on with a whitewash or paint brush. Walls thus coated are proof against dampness.

Good Health.

Sprains.

Or strains of the joints are very painful, and more tedious of recovery than a broken bone. What we call flesh is *muscle;* every muscle tapers down to a kind of string, which we call cord or sinew. The muscle is above the joint, and the sinewy part is below it or *vice versa*, and the action is much like that of a string over a pully. When the ankle, for example, is *"sprained,"* the cord, tendon, or ligament (all mean the same thing) is torn in part or whole, either in its body or from its attachment to the bone, and inflammation—that is, a rush of blood to the spot—takes place as instantly as in case of a cut on the finger. Why? For two reasons. Some blood-vessels are ruptured, and very naturally pour out their contents; and second by an infallible physiological law, an additional supply of blood is sent to the part to repair the damages, to glue, to make grow together, the torn parts. From this double supply of blood the parts are overflown, as it were, and push out, causing what we call *"swelling"*—an accumulation of dead blood, so to speak. But dead blood cannot repair an injury. Two things then, are to be done, to get rid of it, and to allow the parts to grow together. But if the finger be cut, it never will heal as long as the wound is pressed apart every half hour, nor will a torn tendon grow together if it is stretched upon by the ceaseless movement of a joint, therefore, the first and indispensable step, in every case of sprain, is perfect quietude of the part; a single bend of the joint will retard what Nature has been hours in mending. It is in this way that persons with sprained ankles are months in getting well. In cases of sprain then, children who cannot be kept still, should be kept in bed, and so with many grown persons.

The *swelling* can be got rid of in several ways; by a bandage, which, in all cases of sprain should be applied by a skillful physician—otherwise mortification and loss of limb may result. A bandage thus applied keeps the joint still, and keeps an excess of blood from coming to the part, and by its pressure, causes an absorption of extra blood or other extraneous matter.

Another mode of getting rid of the swelling is to let cold water run on the part injured for hours.—*Journal of Health.*

What is a Cold?

On a less authority than the London *Lancet* would the theory be credited that the resolve of a person not to take cold is ample protection against having one. "It is startling to discover," says the *Lancet*, "how little we know about the commoner forms of disease. For example, a 'cold.' What is it? How is it produced, and in what does it consist? It is easy to say a cold is a chill. A chill of what part of the organism? We know by daily experience that the body as a whole or any of its parts may be reduced to considerably lower temperature than will suffice to give to man a cold if the so-called chill be inflicted upon the surface suddenly. Is it then the suddenness of a reduction of temperature that causes the cold? It would be strange if it were so, because few of the most susceptible of mortals would take cold from simply handling a piece of cold metal or accidental contact with ice. The truth would seem to be that what we call cold taking is the result of a sufficient impression of cold to reduce the vital energy of nerve centers presiding over the functions in special organs. If this be the fact, it is easy to see why nature has provided the stimulus of a strong fit of sneezing to rouse the dormant centers and enable them at once to resume work and avoid evil consequences. This explains why the worst effects of cold do not, as a rule, follow upon a 'chill' which excites much sneezing. Shivering is a less effective convulsion to restore the paralyzed nervous energy, but in a lower degree it may answer the same purpose. The shivering that results from the effect of a poison on the nervous centers is a totally different matter. We speak only of the quick muscular agitation and teeth chattering which occur whenever the body is exposed to cold and evil results do not ensue. It follows from what we have said that the natural indication to ward off the effects of a chill is to restore the vital energy of the nerve centers, and there is no more potent influence by which to attain this object than a strong and sustained effort of the will. The man who resolves not to take cold seldom does."

Crude Petroleum as a Remedy in Consumption.—Dr. M. M. Griffith, of Bradford, Pa., reports some astonishing results obtained by the administration of crude petroleum to consumptives. He claims that out of twenty-five cases of well marked tuberculosis so treated twenty are to all means of diagnosis cured; the rest have been materially benefited; and none have been under treatment more than four months. The nausea attending the use of ordinary crude petroleum led him to adopt the semi-solid oil that forms on the casing and tubing of wells. This, made into three to five grain pills by incorporating any inert vegetable powder, was administered from three to five times a day in one pill doses. This first effect, he says, is the disappearance of the cough; night sweats are relieved, appetite improves, and weight is rapidly gained. It is to be hoped that Dr. Griffith has not mistaken some self-limiting phase of throat or bronchial disorder for true consumption of the lungs; also that continued trial of the alleged remedy will justify the high opinion he has formed in regard to its efficacy.

Dangerous Curiosity.—It is the most natural thing in the world, when you have gone to bed, to get up, run to the window, hoist it and look out at an alarm of fire or any unusual noise or clamor going on outside. A lady was roused from her sleep by a cry of "fire;" her chamber was as bright almost as day when she opened her eyes. She went to the window, and soon saw that it was her husband's cotton factory. She felt on the instant a shock at the pit of the stomach; the result was a painful disease which troubled her for the remainder of her life, a period of nearly 15 years. A young lady just budding into womanhood was called by the sound of midnight music to the window, and in her undress leaned her arm on the cold sill; the next day she had an attack of inflammation of the lungs which nearly killed her. She eventually recovered, only to be the victim of a life-long asthma, the horrible suffering from the oft-repeated attacks of which, during now these 20 years, is the painful penalty, to be paid over and over again as long as life lasts.

Digestion is a complex act. Meat is digested in the stomach; feculas, already modified by the saliva, achieve their transformation in the intestines, while fatty matters are only digested in the intestine. Hence the explanation, why some persons can digest meats and eggs without difficulty, while their stomachs are rebellious to feculent and fatty substances. Individuals on the other hand, who cannot eat veal, can partake of fatty preparations and pastry without inconvenience. Thus each organ has its role, and on their state of health depends the integrity of digestion. Inhabitants of cities suffer most from dyspepsia, that is, from an alteration of the digestive ferment.

Nearsightedness and the Color of the Eyes.—M. Nicate stated, at the meeting of the French Society for the Advancement of Science, that as one of the results of his examination of 3,434 eyes in relation to myopia, at Marseilles, this defect was observed far more frequently in light than in dark eyes, blue and gray eyes furnishing 18%, and black and brown eyes only 11.27%.

The Week.

The wintry character of the weather has passed away, and we are now enjoying a spring-like mildness with bright sunshine. There is hut little animation in mercantile circles, with no outlook for immediate improvement. Every body is hoping and waiting for prosperous times. The mines are shipping ahout the usual amonnt of hullion, and should he appreciated as being our main reliance for coin during this stagnation in all other matters. New mines are being discovered and opened, and through this source comes a ray of promise for the improvement in the future. The rains have thus far heen ample to eecure good crops in the coming season, and this, in combination with our mining yield give promise of hetter times, but not soon enough to avail for present wants. Assessments are now more plentiful than dividends, hut we hope they may cause a turning of tbe ecale when the work they are to pay for is accomplished.

The Legislature now in session bas so far not produced any striking results of henefit to the community, and consequently not of much profit to themselves.

The great item of interest was the eclipse, which caused much comment, and set many to looking heavenward, whoee gaze is seldom turned thitherward. The sky was propitious for a clear view of the pheuomenon, and it is to be hoped that the anticipated results from the accumulated observatione of scientists when made known may add greatly to our knowledge of solar and lunar matters.

THE laying of the corner stone of tbe new Masonic Temple was celehrated last Saturday at Oakland.

R. J. BARNET, an ex-Justice of tbe Peace, killed himself in San Jose last Thursday evening.

SINCE the 8th instant the fighting hetween the Alhanians and Montenegrins hae heen inceesant.

HON. EUGENE FAWCETT, Superior Judge, died suddenly at Santa Barbara Friday morning.

"Vapor Assays."

In a report on some mines situated in the Coast range of Marin county, some statements ars made with reference to assays, which have excited soms discussion among the assayers of this city. Ore from the locality mentioned tested hy Wm. Gardnsr, assayed in gold and silver $36 per ton, and assayed hy J. H. McCrorey $96.61 per ton, hoth lots heing from 700 pounds crushed and sampled hy Mendheim and Hofmann. Mr. C. H. Swain, who made the report on the properties referred to, says: "A vapor assay made by an entirely uew discovery shows wonderful and startling results, which I need not refer to here, as any of the other assays show sufficient gold to pay well for working the ore."

In a supplemental report this gentleman says: "There having heen eome difference of opinion among assayers and others as to the value of ores from these mines, and for the purpose of satisfying myself hefore allowing my report upon them to be distrihuted that they do contain gold and silver in large and paying quantities, I have assayed from one of the sample hottles referred to in my report in two ways, with results as follows:

"No. 1. Treated with chemicals, and after being acted upon for 16 hours, put into a strong fire and partially fused, after which a fire-assay gave:

Gold	$210 95
Silver	5.65
Total	$216.60

"No. 2. Treated direct from same sample bottles with the use of no chemicals, and hy an ordinary hre-assay gave:

Gold	$ 60.27
Silvsr	5.65
Total	$ 65.92"

Such an extraordinary statement would not go unquestioned of course, and the inference is the gentleman was either mistaken, did not know how to make a fire assay, or had made a wonderful discovery—a *reactivo*. And thie is etranger still, when we learn that numerous assays have heen made of ore from the locality in question, hy Mr. Thos. Price, Mr. Irelan and Messrs. Kustel & Riotte, neither of whom have heen ahle to find anything in the rock, or at most hut a trace of silver and no gold; they working of course by ordinary fire assay.

It is argued by those interested in the property that the hre assay will not show the yield of this particular clase of rock owing to the peculiar nature of the rock itself. It is said to be "green" as yet, and not fully formed, and carrying the metal partly in a "liqnid state." The ore is said to carry 13% of moisture, while that from the Sierra Nevada range usually has only 9%. The ore, therefore, to he properly assayed must be prepared hy a peculiar treatment.

We are informed, however, hy a thoroughly competent assayer of thie city that he tested the ore strictly in accordance with the written instructions of Mr. McCrorey, who has devised the new system, and that he failed to get any returns. And this not only with one lot, hut with several different lots, all from the same samplings as referred to ahove. The parties interested, however, maintain that by their new process of assay they can get results far ahove those given hy mere fire assay.

View of the Eclipse from Table Mountain, Fresno County.

[Written for the PRESS by J. W. A. W.]

The Table mountain of Fresno county, very similar in every way to its namesake in Tuolumne county, ie located ahout a mile and a half east of Millerton, former county seat of Fresno, and a mile in the same direction from old Fort Miller. Its northern base extends to the south hank of the San Joaquin river, at the point where that stream makes its exit from the mountaine proper into the foothille of the Sierra Nevada. In all its parte—for though extending on a general level for several miles northwest and southeast, it ie somewhat divided on top hy denudation, though to no great depth—its upper surface is on a general level, embracing eight or ten square miles in area. The hight of this elevated mesa land ahove the old fort, whose strongly-huilt adohe houses and the surrounding land—now the property of Judge Hart—rest in a well protected nook on its northeastern hase, is some 1,100 or 1,200 feet, and at least 400 feet more ahove the eea.

Like the Tuolumne Table Mountain,

It ie capped at several pointe with more or less shattered columns of dark brown trap or hasalt, such as exists in few places in California. This feature, and its extremely flat surface, make it a conspicuons ohject from many points on the San Joaquin plains. From its northern points, a remarkably fine view is had of the river at least 12 miles westward, as its hroad and glittering waters hasten in their winding course through low hottom lande hounded by high hluffs to the vast level valley to which it gives its name. The view to eastward is still wilder, and truly grand, as the eye followe the stream for ten miles ahove Millerton, in its oddly serpentine course in a deep gorge where the river hed is quite 1,000 feet helow you, until it is lost to view among the higher ridges which rise as if in tsrraces, one ahovs another, until from 50 to 55 miles distant the great summit ridge of the Sierras is distinctly ssen, its passes over 10,000 feet high, its peaks over 13,000, all alike at this season covered with a dense white sheet of snow, that extends far down among the pine-clad sides of the lower ridges.

Prof. Davidson having shown in his valuahle paper on the total solar eclipse of January 11th that

Its Central Line

Would pass directly over Millerton, your corrspondent selected one of these points of Tahle mountain from which to view the various interesting phenomena of so rare an event as a total eclipse of the sun. This choice was made especially, that the attractions of fine mountain scenery and a good visw of the movement of the dark shadow of the moon, fromsouthwest to northeast over some 115 miles of its course from crest to crest of Coast range and Sierras, might he added to the usual features of such ohscuration of our source of light and heat.

On Time, as They Always Are,

The sun and moon hegan the performance, at Tahle mountain, not far from 2h. 50m. The total eclipse occurred about 3h. 57m.; the end ahont 5h. 4m., or a few minutes after sunset, for we distinctly saw that the northern limh of the eun was slightly eclipsed to the left as it sank below the Coast range mountains which here bound the western horizon and have ahout twice the altitude of our point of obsservation.

By 3:40 P. M. the darkness had so increassd that the whole scenery of mountain and valley was covered with that greenish light peculiar to solar eclipses, and a few minutes later all shadows gave out a weird appearance, fringed apparently with a faint halo. The lowing of cattle on the surrounding hills gave evidence of the usual impression on them.

At last an intense darkness over San Joaquin valley to the southwest showed that the line of totality had reached there. All at once

A Broad Spot of Inky Blackness

Rested a few seconds on the Coast range monntains and then hegan its steady sweep across the plains toward us. The glimmering reflection on the river's glassy surface, which continued to show faintly in the preceding twilight, suddenly disappeared and the moon's dark shadow was upon ue. On hoth sides of the penumhra, a dim twilight appeared, brightening gradually towards the north and south. The impression produced by this regularly moving shadow can never he lost through life. The stillness was profound. Not a hreath of air was stirring, hut the atmosphere was evidently chilled. The thirty-five seconds of totality allowed but little time for ohservations. But there was the dark round figure of the moon, snrrounded by a heautiful corona, uniform in width and brightness, and reminding one in tint of the

Whitenees of the Electric Light.

Next we looked for the five planets that were to he visihle. There were Jupiter, Saturn and Mars, to eastward in the order named, the first perhaps 35° from the sun; the second some 50°; the third 75° or more. But to westward where Mercury and Venus were to he seen, enough white clouds had formed to ohscure the field of vision, and we could see none but the three planets named—evidence of a rather hazy atmosphere. Indeed, immediately after sunset, the eky was suddenly overcast with dark clouds which would have entirely hidden the eclipse, had they come an hour or two earlier. No sooner did the narrow, distinct, not flickering line of the sun appear on its lower limh, than we could see the dark shadow move rapidly eastward, across the mountains, until it passed over the snowy summit and was lost to view forever. Slowly, as

The Genial Light and Heat of Old Sol

Had left us, it returned to its normal condition, hefore snnset, to the evident surprise of animated nature, and certainly to the delight of man. Thus ended one of those grandest phenomena of nature, such as is rarely seen more than once in a lifetime hy any one human heing. It is worth recording, that the naked eye revealed no indioations whatever, from our point of observation, of the coruscatione of light and other phenomena, known as Baily's Beads—a fact no douht to he accounted for hy the extreme calmness of the atmosphere at the time and place, as suggested hy Prof. Davidson.

It is to he hoped that our well equipped astronomers were ahle, from their high point of ohservation in the Santa Lucia mountains on the coast, to arrive at a nearer solution than ever hefore of the existence or non-existence of the Vulcanites, and similar prohlems of interest in their exact and instructive science.

IN the State Assemhly, on Saturday, the first hill of the session was passed—an act repealing the so-called "Rogers Act," in regard to Water Commissioners. There was a long debate, hut only one vote against the hill.

THE capital of the Giant Powder company has heen doubled, and the dividend on the new etock of 75 cents per ehare is equal to $1.50 on the old stock.

FRANK LESLIE, the publisher, died at New York last Saturday.

On Tempering.

[Written for the PRESS by R. GRIMSHAW.]

There are soms recently discovered facts conerning tempering which are not as widely known as their interest and importancs should demand. These facts relate to the temper, use and working of steel; and curiously enough they all have been discovered hy analogy from exprriments made with *glass*.

For a long tims it was not known that tempering gave steel anything more that a hardness and elasticity greater than untempered metal. But later it was noted that in tempering, steel loses its crystalline structure to take a confused and irregular arrangement of particles, a sign of increassd power of resistance to rupture. Crystalline hodies are easily hroken hetween the crystals. We may say that tempering, while entangling and compressing the amorphous (that is, uncrystalline) molecules, gives to the hody a much greater tenacity.

Caron likened tempering to the action of hammering or hot-forging, operating on the central nucleus hy the contraction of the quickly cooled exterior layer. Sudden cooling hinders crystallizing (just as agitation does in an alum solution) and causes compression and coudensation. This is proved at the great steel works of Creusot, where targets of tempered steel show the interior layers to he compressed while the outer ones are *extended* under the effort. An oil or water hath will shrink masses too large to he compressed by hammering. Tempering resemhles long-continued hot-hammering, also, in taking away the large crystals. Cooling under pressure does tbe same thing.

A series of important experiments were made hy Mons. Leger, to see whether *form* had any influence upon the internal qualities of hodies to be tempered. These studies were best made with glass, in which not only the elasticity and sonorousness, hut the tenacity, is quintupled hy tempering; while in steel the increase is only one-half. Glass has this advantage, that any etate of contraction or dilation is clearly shown by polarized light. Through a Nicol prism parts in tension show iridations or milky streaks. A tempered plate presents a wrinkled appearance. Leger has shown that the same iridescent figures and waves are produced in tempered glass, and hy compressing a similar piece of ordinary glass. Polarized light, passing parallel to the axis of a tempered glass, solid or hollow cylinder, shows concentric iridescent circles, with a crose either black or white, as the diametral plane of the polarizer makes 180° or 90° with the analyzer. Rotating changes the crosses to hyperbolas. (Fig. 1.)

Centrally compressing an untempered cylinder, hy either a hlow or a steady screw pressure, we get the same spectra. Shifting the pressure to one side, the circles *ovalize*, and near this point. The same result is ohtained hy reversing—that is, heating and suddenly cooling *the center*.

To prove that the rings are caused hy the exterior layer of the tempered oylinder, cut away enough stuff to leave only a square or polygonal prism, and the iridescence is shown to he a square or polygon, having its points of greatest compression at the angles. (Figs. 2 and 3.)

Compressing an untempered cylinder at a diameter shows a douhle series of iridescent ellipses all tangents to each of the pressure points—the system snrmounted hy a dark Maltese cross, and surmounted hy a milky ellipse, as long as the pressure diameter and half as wide. (Fig. 4.)

Compressing the same cylinder in two diameters at right angles, this last system douhles up symmetrically. (Fig. 5.)

If a tempered square plate or prism be examined it will show at the four corners strongly iridescent "peacock'e eyes," reaching farther or not so far across the diagonals, according to the temper. From one angle to the other, along the sides, are iridescent archee or festoons convex centerwards. Following the two diameters normal to the sides, is a cross which is white or hlack according to the angle of the polarizer. The squares between the "peacock's eyes" and the side arches and the cross are milky. (Fig. 6.)

A trapezium gives a spectrum merely modified according to its exterior form. (Fig. 7.)

Just in proportion as one heats (and thus expands) the center of an untempered plate, the dark cross and the milky squares develop.

To get the same effects hy artificial, that is, mechanical compression, Leger tried many experiments. In all these the "peacock's eyes" developed at the points of great pressure, and the neutral areas where the pressure did not extend were very clearly defined.

The shorter axes of the ellipses always lengthen with the pressure, proving the latter to extend further, laterally; but rupture always takes place along the longer axis.

To explain these images, one may say that two equal forces acting in opposite directions transmit their action from one to the other across a more or less elastic hody, the areas acted upon heing ellipses longest in the direction of the two forces. When there are irregularly placed points of pressure, the force lines are seen plainly curving.

In all the polarized images the iridescent and milky parts appear to indicate molecules compressed or dilated in every direction. The dark lines indicate compression in one direction and expansion in anotber. Fissures or cracks gen-

erally follow these dark lines, and scales detach themselves along the lins of the most lively iridescences.

Tn get by the compression of a square of untempered glass the same spectrum as a tempered sqnare gives without compression, it must bs uniformly pressed along the sides, and also diagonally. This shows that tempering acts liks a perfect exsternal compression. Expausion hy heating gives polarized tempering figures with nrdinary glass, aud ono can also reproduce them by properly directed external pressuro.

Experimenting with blocks of all sections, ws find iu general at ths snmmits or ponts of greatest teusion peacock's eyes of lively irisations, with hatchiugs of milky light. From one tip tn another, like side arches, iridescent festoons more or less convex. Dark branches, always derived from the hyperbola, and sep arated by milky fringes, leave the csntral nnclens and recut ths sides.

If a tempesd bar bs cut in sliccs, each fragment will present, in face and profile, spectra similar to thoso of the entire bsr, although loss vivid; jnst as in a magnetic bar eacb slice would be a perfect, though weaker magnet. If the body be transformed lengthwise by grinding, turning, filing, milling, etc., it is the samc; but if the uew section be dissimilar from the first, there will be partial fogs ou the spectra.

To study the true polarized spectrum of a given form, it must, then, be certain tbat the body was tempered in that form.

Bodies made from othcr tempered forms do not, after great reheating and new tempering, show the spectra of the first form—showing, also, how difficult it is by any exterior heating to thoroughly *untemper* a body; to destroy in the whole mass a state or a molecular arrangement once acquired.

Thie brings us to an important question: The importance of tempering after shaping, whcn the molecules, coming from the pasty etate, submitted without cees to successive hammerings or reheatings, have kept their amorphoue stato clear into the center, and offer themselvee to thc action of tempering, more malleable and moro homogeneous than they will be fonnd again after some of the particles have arranged themselves in crystals. Why is it that tempering rounds both salient and re-entrant angles?

If we imagine a layer of molecules equidistant from the outer layer of a tempered prisms we will lind that all the particles except those at the corners are heated on one-half and cooled nn the opposite. But those at the corners are cooled over tbree-fourths and heated from one-fourth nnly; hence are *driven* in by the outer laysrs. In the case of a T piece, the molecules in the re-entrant angles are heated along three-fourths and cooled over one-fourth only; hence they are driven *outwards* from the hot nucleue and the angle rounded in this case too. (Figs. 8 and 8.)

A cylindrical bar has its plane bases changed to spherical segments in tempering. A tempered hollow cylindrical has all its edges rounded, and if very thick, the bore ie "hour-glassed." (Figs. 10 and 11.)

If we were to temper a cylinder in the solid, and then bore it (and impractical case) the hore would have met the stratified layers towards the base, perpendicularly, or at a great angle, which would have caused a lack of cohesion particularly dangerous in certain applications.

The rounded hases modified hy tempering, with their discordant stratification, are not as strong as the greatly compressed parallel layers, and in instances where there was need of extreme resistance at the ends, it would be prudent to turn or grind off all those parts weakened by this discordance, and to present the plane base, where all the layers being concentric, are firmly held together. The grain would be finer and the material stronger from this oause.

A ring, as a fillet on the face of a cylinder, disturbs stratification in tempering and may actually cause that degree of weaknese which it was placed to prevent.

It is very difficult to heat the central portion sufficiently to destroy its crystalline structnre, once acquired, without melting the layers. In the reheating furnace, as in the tempering hath, it ie often neoessary to turn the pieces on their axes and cnd for end. Without this, the side turned towards the arch or the hearth, that next the door or the bridge, would present great differences. Also, during tempering, the lower side is much more energetically cooled than the upper, on account of the upward direction of the ascending current of liquid.

The supports, during tempering, exert a considerable influence, according to their specific heat, and whether or not they prevent the transmission of heat or the circulation of the cooling bath.

There is shown in tempering anotber molecular arrangement, only appearing with excessive temper.

DeLuynes remarked that the familiar "Rupert'e Drop" would, if sawed across its equator, separate into two portions terminated by cones. Sections to right and left of this line also gave conical terminations, but pointing to the center of the drop. The same disposition of symmetric cones was found in a bar of tempered glass.

Leger observed the same law and the same pointed fractures in tubes, flasks, bottles and sheets of tempered glass broken by over-flexion.

Bars of hard tempered glass, breaking spontaneously, show not only conical fractures in the central nucleus, but a fibrous texture in bnnches of needles converging towards the apex of the cones. Bars of certain tempered steel, tested for teusils strength, show ths same conical fractures and silky surface. This is because each molecnls was, in cooling, pushed towards the bars, and also towards the center of leugth, the resultant being these cones of fibers. The acuteness of the eono will depsnd on the proportions between the two forces, and hence upon tbs proportions nf the bar.

We may conclnde by saying that glass, cast iron and steel have comparabls aspects under fracture. Tempering hrings steel from coarse grain and large crystals to fins grain and that silky textnre spoken of by Chernoff, which is caused by tbe molecules being welded togsther.

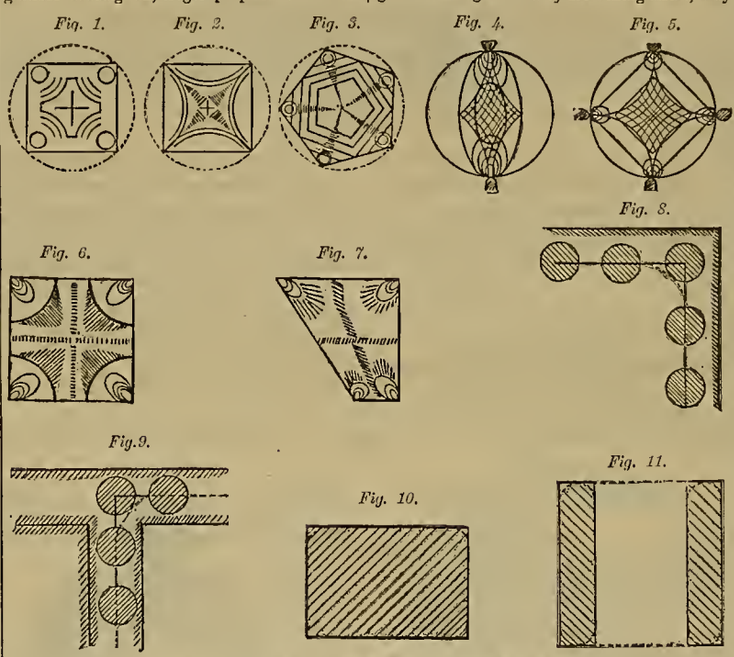
Elasticity, tenacity and sonority develop by temper the same in glass and in steel.

Under the same conditions, sonorons vibrations, on either a glass plats or a steel disk, affect the molecules the sams and maks the same nodal lines. Why would not mechanical vibratious affect tbs ons exactly as tlie othsr?

As a general precantion, expcriencs with glass shows, by analogy, that to get the effect of temper with the greatsst security, *tempering of steel must be done after all shaping or other working*—after casting, forging, or continual hammering, and at least after superficial heating of the envelope cooled by radiation and by contact with the air.* If it bo necessary to completely reheat the mass, it must he donc gradually and eqnally; and to avoid quick separations between the nucleus and the envelope, to turn the piece ahout, change its points of support, and in any case to make the heat penetrate the mass by hammering; not to temper too many pieces at once and thus cause too quick or too great compression; and to givo every opportunity for gradual cooling off, Legsr proposes to uso an crnss section shonld be elliptical, or rectangular with well roundsd edges.

For swords, bayonets, etc., to resist bending, they should not bs tempered in triangular or cross sections, as that tends to sever the ribs about the central nucleus and simply leave thres or four strips of fibers badly fastened together. It would be better to temper while elliptical, and to mill out the gutters.

And now for pieces destined to receivs great interual pressure, as cannons. There is needed tbe greatest symmetry and homogeneity in the concentric layers, and thns all hoops, fillets, etc., should bs avoided, and thsro should bs left at each end a hemispherical piece to bo cut off later.



STRUCTURE OF STEEL IN TEMPERING.

Active Labor an Evidence of Prosperity.

When the laborsrs ars receiving a fair rate of wages, and ars constantly employed, it may be regarded as a surs evidence of prosperity. Labor, intslligently applied, is ever productivs. Men cannot work with the determination of succeeding in their exertions without producing something which has advanced the value of the crude material employed in their work. When the fiat was uttered that man should earn his hread hy the eweat of his brow, it was not given forth in opposition to the great principle of the value or utility of labor. It was uttered in full accordance with the law that work is productive, and that a just compensation is consequently due to the worker.

As society is now constituted, it is incumbent upon all to be producers. Those who fail in this duty, become a dead weight upon the progress of the age. If they are willing idlers, they auxiliary bath of steam; to commence with an easy temper and work up to a higher.

The supports, in heating or in cooling, should not prevent regular and uniform diffusion of heat, lest they cause deviations of the nodal and isothermal lines and eccentricities unfavorable to durahility.

Ae regards the form of pieces subjected to temper, they should be as free as possible from angles, edges, fillets and grooves, shoulders, sudden variations in diameter or sudden bends. Otherwise there may be expected a weak spot near one of these faults. In a word, the nearer the better the approach to continuous spherical and cylindrical forms, and to pieces made up of these simple geometrical forms, which cause the greatest possihle interior cohesion.

It may be advisable even to give these forms temporarily for the tempering stage; subsequent milling, filing, grinding, turning, etc., will not change the internal grain. It may often be well to lose even the hard outer skin, to get homogeneity and cohesion in the mass. According to the intended use of a tempered piece—whether for shock or for preseure, pulling, hending, twisting, internal pressure, etc., we may look into the influence which the state of the welding can hare.

A head used for percussion should have a hemispherical end or very gradual curves. If sharp edges are wanted, as for a punch, the head can be cut off in a lathe as poor stuff; the good material being exposed behind the base of the hemisphere.

For a graver or chisel, the cutting portion is got by working away four faces from the rounded and tempered end, so as to have the greatest homogeneity possihle with a etraight base. The must, and do, suffer the penalties which slothfulness entails upon its adherents. If they are unwilling idlers—idle because no man giveth them work to do—still the pains and penalties of inertia are attendant upon them. Man must work, or must suffer because he does not. If he is a voluntary idler, though possessed of sufficent means of support, nature inflicts upon him a loss of energy, a failure of health, and, in general, a moroseness of disposition, which embitters his existence. If an involuntary idler, he suffers from the privation which his unsupplied wants create.

The law that man shall work is an inexorable one. It is imperative that he shall find occupation. He cannot escape from its imperious necessity. His own vitality as well as the vitality and welfare of othere depends upon his fulfilling the necessities of his destiny to work. Thou *shalt* earn thy hread, was the dictum of Omnipotence. There was no leniency in the strong decree of justice. The mandate was inflexihle. It must be oheyed.

Still it was not harsh. It was tempered with mercy. It was commingled with blessings, and adorned with good. It was replete with benefits and overflowing with advantages. Prominent amoug the henefits is the prosperity attendant upon active labor, and the healthy condition of the worker. These two leading blessings of the human race would not and could not exist without labor.

The nations that have held the largest corps of laborers have always been the most powerful and the most successful. They have lived up to the requirements of the laws of cause and effect, and have fulfilled the exigencies needed for productiou. Their labor has been materialized into solid wealth. Their wealth has given them power. Their power has produced stability. It is iucumhent therefore upon all governments to foster and sustain the cause of labor, for it ie the basic etratum of their existence.

*Steel, after forging and reheating, if left to itself, "tempers" like glass, but irregularly on account of the air currents. This often causes the fracture of pieces when cold, and from no apparent cause. To get an untempered steel, the mass should be cooled as in a hot sand bath. Inversely, to get a *well* tempered mass, natural temper should be avoided and even neutralized by reheating.

Mining and Opinions Concerning Metals Over two Centuries ago.

It is curious as well as interesting to look back through tbe psges of old authors to the state aud position of mining over 200 years ago, and even back into more remots periods. Some recent iuvestigations which we wers making upon tbe methods of reducing ores, led ns to investigate tbis field of by-gone years, and we were surprised at the similarity then existing on many points which are common at ths presnt day. How earnestly and with whst simplicity, both of thougbt and diction, did thoso old pioneers in miniug express their views. With what commendable brsvity they portrayed their descriptions of the various ores that passed under their observatiou. How wisely cautious wers they in their statemsnts; and, at the samo time, how credulous and superstitious withal. With what implicit faith they dwelt "upponne the subtile essence or spirritte of lifo contaynned in ye unstallc;" and, blending much that is vague and visionary with the limited class of understood facts before them, they present to the mind of the reflecting a lesson of due humility, lest in days to come the opinions now so seemingly true may he known to be weak and chimerical. Many are the pagee they transcribed to prove the existence of a "spiritual substance" from which all metals are produced. They believed that the soul or essence of gold possessed the power or property of transmuting all the more base metals into its own valuable substance. Silver stood next in tbe scale; it could not transmute tbe lower metals into gold, but it could hring them up to its own quality, and all other metals could raiss those below them to their own standard, but could not arise beyond it.

They helieved that the soul or essnce of metals arose in the form of a vapor, sometimes visible, at otber times invisible, and settling upon the sides or in the crevices of the vein, elaborated itself by its vital principlo into a true metal; and that when tbe truo metal was thus deposited, it lost its vital principle and became dead. All substances which had reached their true metallic state, either by natural or artificial means, had lost their vitality. This view they drew from their labors in the laboratory, where the analysis of ores and the reduction of metals was accomplished by the action of heat; and knowing the impossibility of animal existence being maintained in such elevated temperatures, they believed the extreme heat destroyed the vitality of the metals also.

Perhaps a few quotations setting forth the ideas they held, as mentioned above, may not be uninteresting to those who have never met with the ancient tomes, or the views of the earlier writers on mining. First we will open "Metallographia or an History of Metals," by John Webster, published in London in 1671, and passing by the laudatory dedication "To his Highness Prince Rupert, Count Palatine of the Rhyne, Duke of Bavaria, etc.," and glance a moment at the preface: "Courteous reader, expect here no flonrishing frontis-piece to allure to the buying of this untrimmed and unpolished piece; no, not so much as the author's picture, who never yet was so far in love with his earthly tabernacle as to he at the charges to have it drawn or cut in copper. Thine own desire after this kind of knowledge, and the plainness of the subject, are the greatest motives that I have to lay before thee to move thee either to huy or read." With what becoming modesty does he make his bow to the public and to his "courteous reader;" a line of policy from which he quaintly deviates as he progresseth in hie tome: "I very well understand that I shall undergo no emall censure for taking upon me to meddle with such abstruse matters, * * * and however they may censure I shall pass by it, * * * and shall modestly tell them that it is above 35 yeare since I first learned a course of common chymistry under old Johannes Huniades; and have been and am a continual reader of and studier in the best authors that have written in mystical philosophy; and therefore, let none bc too censorious of what I know, or what I know uot, in this abstruse science, but weigh the authorities and reasons that I lay down, and accordingly judge of what I write."

Somewhat of a liberal, too, was he, or would have been termed such at the present day, for he says: "Who am myself no lover of dogmatizing, and have long wished, and am now most glad to see a way set up for the promoting of experimental philosophy, that men's judgments may no longer he fettered in scholastic chains, nor always kept in the prisons of academick opinions."

Josephus Acosta saith: "The wisdom of God hath made metals for physick, and for defence, for ornament and for instruments for the work of man."

The miners of those days had much of the same inherent roguery as ohtains among their class at the present time: "So cunning are the minere that if they find any vein of ore that may contain so much of silver as would make it a mine royal, they will not let it he known, hut presently beat it, and mix it with their softer ore, pretending that one will not melt without

CONTINUED ON PAGE 44.

Bide Your Time.

Every man must patiently bide his time. He must wait. More particularly in lands like my native land, where the pulse of life beats with feverish and impatient throbs, is the lesson needful. Our national character wants the dignity of repose. We seem to live in the midst of a hattle, there is such a din, such a hurrying to and fro. In the streets of a crowded city it is difficult to walk slowly; you feel the rushing of the crowd, and rush with it onward. In the press of our life it is difficult to he calm. In this stress of wind and tide all professions seem to drag their anchors, and are swept out into the main. The voices of the present say—Come! But the voices of the past say—Wait! With calm and solemn footsteps the rising tide hears against the rushing torrent up stream, and pushes hack the hurrying waters. With no less calm and solemn footsteps, nor less certainty, does a great mind bear up against public opinion, and push hack the hurrying stream. Therefore, should every man wait—should hide his time. Not in listless idleness, not in useless pastime, not in querulous dejection; hut in constant, steady, cheerful endeavors, always willing and fulfilling, and accomplishing his task, that, when the occasion comes he may he equal to the occasion. And if it never comes, what matters it to the world whether I or you, or another man, did such a deed, or wrote such a hook, so he it the deed and the hook were well done. It is the part of an indiscreet and troublesome ambition to care too much ahout fame—ahout what the world says of us; to he always anxious for the effect of what we do and say; to he always shouting, to hear the echo of your own voices! If you look ahout you, you will see men who are wearing life away in feverish anxiety of fame, and the last we shall hear of them will he the funeral hell that tolls them to their early graves. Unhappy men, and unsuccessful, because their purpose is not to accomplish well their task, hut to clutch the "trick and fantasy of fame," and they go to their graves with purposes unaccomplished and wishes unfulfilled. Better for them, and for the world in their example, had they known how to wait. Believe me, the talent of success is nothing more than doing what you can do well, and doing well whatever you do—without a thought of fame. If it come at all, it will come because it is deserved, not because it is sought after. And, moreover, there will he no misgivings, no disappointment, no hasty, feverish, exhausting excitement.—*Longfellow.*

THE Hidden Treasure gravel mine at Sunny South, has yicldcd over $98,000 during the past year, $37,000 of which has been divided in dividends. This is one of the many instances of good paying mines in Placer county.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued. wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare hook on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and whcrefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple or der. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, $7.50

TO APPEAR SHORTLY.

Crimshaw on Saws.

History, Development and Action, Classification and Comparison, Manufacture, Care, and Use of Saws of all kinds. 8vo. Illustrated. By ROBERT GRIMSHAW.

This thorough little work, impartially written in a clear, simple and practical style, and supplemented by valuable tables, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small Hand, Sash, Mulay, Jig, Drag, Circular, Cylinder and Band Saws, as now and formerly used for cross-cutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With Appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc.; tables of gauges and other valuable information. Elegantly printed on extra heavy paper. Subscription price, $1.50. Orders for first edition received now.

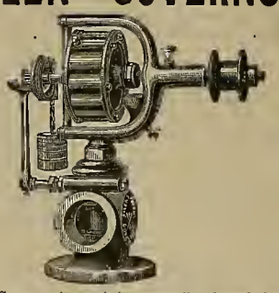
ALLEN GOVERNOR.



This Governor is now being generally adopted throughout the United States and Europe. It is without doubt, the

Most Perfect Engine Regulator in Use,

And will in most cases save its cost several times a year. It is invaluable on a QUARTZ, FLOUR or SAW MILL ENGINE, or in any Manufacturing Establishment, where Regularity of Speed is desirable. By being able to run the engine to its full capacity, these Governors have in many cases added

Ten Per Cent. to the Productive Capacity of a Mill,

Thus saving more than their cost every week in the month. Every Engine to which this Governor is attached will run with the throttle wide open. The speed of the Engine can be changed by a simple adjustment of the weights. It will give a UNIFORM SPEED WITHOUT REFERENCE TO THE BOILER PRESSURE. It is simple in construction and not liable to get out of order.

Every Governor warranted to give perfect satisfaction. Thirty days given for a trial, and if it does not fulfill all that is promised, it can he returned at our expense.

In ordering, state the kind of engine, diameter of cylinder, stroke, speed, and average pressure.

Send for full descriptive circular.

PHOSPHATE SOAP

THE BEST soap for toilet use ever manufactured. BEST because it contains all the excellencies of the most expensive foreign or American soaps without their defects. BEST because it combines strength with delicacy in such a way that its strong detersive qualities do not injure the skin. BEST because it is the result of years of study and experiment in the soap manufacturing business, assisted by modern chemical discoveries. BEST because it contains ingredients beneficial to the skin, which unite chemically with the soap in such a manner as to increase its saponaceous qualities. Every chemist familiar with soap manufacture knows that some ingredients which are in themselves beneficial to the skin cannot be saponified; some are partially neutralized, while others injure the quality of the soap. There are soaps in the market which are to some extent beneficial to the skin, but they are inferior articles for toilet use. PHOSPHATE SOAP is the ONLY article offered to the public which combines all the best elements of toilet soap with medical ingredients beneficial to the skin.

If you wish to make your hands soft buy a cake of PHOSPHATE SOAP, and when that is gone you will buy a dozen and recommend your friends to do the same.

Ladies who wish to make the skin look beautiful and natural should use PHOSPHATE SOAP.

For chapped hands the constant use of PHOSPHATE SOAP will be recommended by all who give it one fair trial.

TESTIMONIALS.

SAN JOSE, September 24, 1879.

To the Standard Soap Co.—Gentlemen:

It affords me pleasure to say to the public that I have used and prescribed your PHOSPHATE SOAP as a remedy in various forms of cutaneous diseases with the happiest results. I am of the opinion that it is the mildest and most perfect detergent that can be used, either for cleansing the skin and leaving it soft and healthy, or for removing the fetor and corroding influences of sores and ulcerations. I should be sorry to be without it in shaving my face or making my toilet, to say nothing of my good opinion of its remedial qualities.

A. J. SPENCER, M. D.

SAN FRANCISCO, Aug. 27, 1879.

Gentlemen:

I received a package of your soap (Phosphate Soap) and it gives me great pleasure to testify as to its superior excellence. As a toilet soap I have never seen anything to surpass it. It also possesses superior remedial qualities. I have used it in two cases of obstinate skin disease, one of intolerable itching, *Pruritus*, the other an *Eczema*. In both great relief was obtained. Its emollient properties are remarkable. Respectfully,

W. A. DOUGLASS, M. D.,
126 O'Farrell St.

To the Standard Soap Company.

SAN FRANCISCO, July 19, 1879.

Standard Soap Co.—Gents:

I have tried your PHOSPHATE SOAP, and have no hesitation in saying that it is the best toilet soap I ever used. My wife has used it and is of the same opinion. I have paid as high as fifty cents per cake for an article in every respect inferior to what you sell for twenty-five cents. HENRY H. LYNCH,
515 Haight street.

The genuine merits of PHOSPHATE SOAP and persistent advertising will force every druggist, groceryman and general dealer to order it by the gross sooner or later. Ask for it in every store. The retail price is 25 cents per cake. We wish to sell it only at wholesale, but in case you cannot find it we will send a nice box of three cakes by mail, postage paid, on receipt of 85 cents in stamps.

Ingersoll Rock Drills.

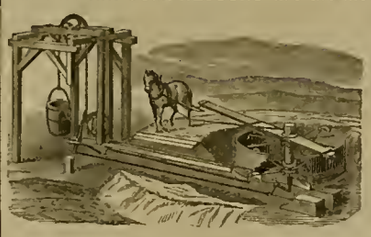
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.
The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

DEWEY & CO.'S

Scientific Press Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

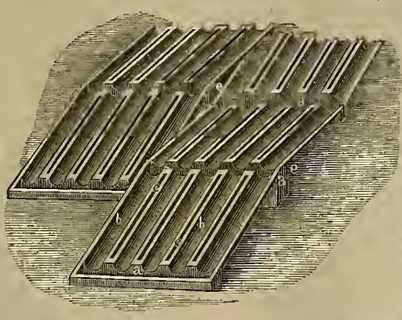
Howland's Under-current, Mill and Sluice Riffle.



This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by *letter.*

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city:
Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Huerne, John Marquis, B. McDougal & Son, Wm. Mooser, Wm. Curlett, Meeker & Banks, W. O. Hoagland, S. & J. Newsom, B. Henrickson.

Mines and Works of Almaden.

Translated from "Annales des Mines"

BY S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (post-paid) 50 Cts. Published and sold by DEWEY & CO., [202 Sansome Street, S. F.

CONTINUED FROM PAGE 37.

of copper on the southeast slope of the Huachucas. The ledge can be traced for 3 miles and is 40 ft in width. Three locations, the Commodore, Jeannette and Bennett have been made. The rock shows native silver all through the specimens, and assays $30 in silver, 65% copper and a trace of gold. Wood and water are abundant and a living spring flows on the ledge. A number of good carbonate ledges are located in this vicinity, but this is the first copper deposit of any extent and value discovered.

On the San Xavier three shafts, 90, 110 and 127, have been sunk, and on the Buena Vista a shaft of 60 ft, showing large bodies of carbonate and galena ore. About 1,200 tons of ore are now on the dumps, and over 300 ft in levels run. Messrs. Gibson & Blade have discovered and located an immense silver ledge in the Sierritas. It is 60 ft in width; there is plenty of wood and water close at hand. Samples of the ore were brought in for assay.

CUSTOM MILL.—Tucson *Citizen*, Jan. 10: Mr. Chas. Isenheck, inventor of the Isenheck process of working ores, has leased Warner's 2-stamp quartz mill, and will commence work on custom ores by his process. He has on hand 3,800 pounds of quartz from the Huachuca. Messrs. Watson & Johnson will bring in 23 tons from their mines on the San Pedro, near old Camp Grant, and Prof. Salazar will have the ore from the Black Metal claim worked soon.

HUACHUCA ITEMS.—*Arizona Citizen*, Jan. 10: The Wisconsin claim, in Ramsey's canyon, Huachuca mountains, is a large vein, carrying Peacock copper ore, which assays from 20% to 50% copper and 35 ozs. silver per ton. A contract is let for 200 ft of shaft and tunnel. At 150 ft the tunnel will tap the vein at a depth of 125 ft. The claim is on the side of the mountain and the ore can be taken out by stoping from the tunnel to a depth of 200 ft, saving the expense of hoisting. There are other claims near the Wisconsin carrying the same character of ore. A tunnel has been run in the Nelly James 18 ft, with good ore on both sides; the ore body is 15 ft in width. This claim produces three varieties of smelting ore, viz: galena, carbonates of copper and gray copper. The yield of the galena is $70 per ton in silver. The carbonates average 60% copper, and $80 to $90 per ton in silver, while the gray copper averages 40% copper and $30 to $195 per ton in silver. The Salinas mine is of the same character as the Nelly James. Work on tunnels and shafts on both mines will be pushed rapidly. There is abundance of pine, fir and oak timber in the immediate vicinity of these claims which will only cost the cutting for smelting purposes. There is also water at the mill site.

COLORADO.

LADY FRANKLIN.—Silver Cliff *Prospector*, Jan. 6: Sulphurets assaying 120 ounces in silver were struck at a depth of 100 ft. The Milk Maid lode, on the same lead, at 60 ft, are drifting for the vein. The wall rock in this shaft runs 23 ounces of silver.

TUSCARORA.—The shaft is down 25 ft. There is a fine body of manganese, with silver-bearing galena. Assays run 18 ounces. This mine is situated one-half mile northeast of Round mountain.

R. E. LEE.—A shaft has been opened 12 ft. At this depth a true fissure vein is disclosed, bearing ore of good character. The ore is iron formation and assays 16% of iron and 26 ounces of silver.

BOUER NEST.—*Register-Call*, Jan. 2: Sinking is progressing on the shaft. It is now 450 ft deep, and makes considerable water, which the pump easily keeps under control. In the east lower drift about 140 ft from the shaft, there is a fine body of ore on which stoping is now progressing. The principal work is sinking the shaft.

FREE AMERICA.—The shaft is 500 ft deep. The bottom is 90 ft below that of the Boulder Nest shaft. It does not make more than half as much water as the latter lode, although there is a comparatively short distance between them. A good vein of ore was recently encountered in the bottom of the shaft, from eight inches to two ft wide of argentiferous galena, carrying white spar, running several hundred ounces in silver.

FREE AMERICA EXTENSION.—This mine is now turning out ore of fair grade in good paying quantities to the lessees, Stevens & Co. They are drifting east about 125 ft from the Free America ground. A mill-run made this week yielded silver at the rate of 150 ounces per ton.

MENDOTA.—The shaft is 63 ft deep. The stope west of the shaft carries a foot of solid ore consisting mainly of galena, and running from 35 to 80 ounces of silver per ton, and from 40% to 60% in lead. The drift immediately east of the shaft carries 6 to 15 inches of scattered and solid ore which appears to be the top of a pocket.

PICKWICK.—The development of this lode near the summit of Saxon mountain, will be fully prosecuted. A tunnel has been commenced on the north side of the mountain which will cut the lode 400 ft deep, at a distance of 400 ft from its mouth. Messrs. McGrath and Hugh have the contract. The tunnel is now in 20 ft. The property is owned by a company from Syracuse, N. Y. Capt. T. G. Cree still retains an interest, and superintends the property. The mine carries rich ore, the lowest run taken out milling 305 ounces of silver per ton. The average is about 1,000 ounces.

TROPIC.—Recent developments on this mine are adding to the value of the property. The ore in the stopes and drifts runs all the way from 2 to 18 inches wide, and is of uniform grade, milling from $80 to $250 per ton in gold, silver and copper.

JOE REYNOLDS No. 3.—Drifting is progressing on the three main levels. Both the upper levels are showing up well in ore. There is nothing in the breast of the lower drift, but the lessees have raised into good mineral from that point. The ore is now becoming more solid, consisting largely of very fine-grained galena and copper pyrites. A late run of ore from Daily & Co.'s ground milled 500 ounces for first-class and 160 ounces for second-class.

PERUVIAN.—The Peruvian is showing up handsomely as development progresses. The shaft is now 75 ft deep, and shows ore all the way down, ranging from 10 inches to 4 ft of a pay vein; consisting principally of bright galena, gray copper and iron pyrites, with some gangue scattered through it. It assays from 50 to several hundred ounces in silver per ton.

MINING ITEMS.—Silver Cliff *Prospector:* The Kohinoor, of Clear Creek, has shown a $4,224-assay. An early opening is predicted for Camp Pitkin next season. The Dunderberg, above Bakerville, is being worked extensively. Judge T. M. Bowen has four men employed on his mines in Summit. Edison made the test for platinum in Decy's new mine in American basin, San Juan. The Stevens mine, near Georgetown, lies at an elevation of 12,500 ft, and is worked all the year round. The Dixie lode, six miles from Idaho Springs, shows a 15-ft crevice of brown quartz sprinkled with gold. The Yankee Doodle mine, on Carbonate hill, has been transferred to the Carbonate mining company for the sum of $300,000. The Michigan lode, in San Juan county, has struck a pay streak of 28 inches, which is yielding gray copper of high grade. The Emma lode property, on Democrat mountain, has recently had a run of ore which milled at the rate of 602 ounces of silver per ton without classifying. Hiram Bragg has completed 150 ft of his contract of 350 ft on the Iowa & Colorado Con. company's mines, in the Summit district.

DENVER.—Silver Cliff *Prospector*, Jan. 7: The Denver mining claim, owned by the Portagee & Colorado mining company, situated within half a mile of the Bull-Domingo, is nearly 100 ft deep and is looking well. They have followed a 10-ft vein of carbonates all the way, which is rapidly changing into fine minerals. The indications are characteristic of galena.

LIMERICK.—The Limerick lode, on the west side line of the Ben Franklin, which has been idle for some time, is being worked, operations having been inaugurated to-day.

KING OF THE CARBONATES.—Work was resumed to-day on the King of the Carbonates, under a 50-ft contract.

BEN FRANKLIN.—Yesterday the valuable mining property at Rosita, known as the Ben Franklin mine, was sold to Chicago parties for $75,000.

MONTANA.

MINING ITEMS.—Butte Mountain *Miner*, Jan. 6: A party of Chinese miners have taken a five years' lease of the gulch, or creek claims, belonging to John B. Sutton, Elias Snyder and others. They are situated on North Clear creek, above the mouth of Missouri gulch. A specification is made in the lease that they can purchase the claims within a certain period of time upon the payment of a stipulated sum. The Chinamen have taken possession of the property under the lease. Jack Needham, one of the old pioneers, on Seaton mountain, Idaho mining district, is in the city. He says that more men are employed in that district than ever before. Work is progressing on the Mack tunnel, which is to penetrate the "true inwardness" of Clifton mountain, as fast as men and means will admit. Ex-Mayor Hartman, of Blackhawk, has a fine vein of ore in the Lucerne mine; the Victor vein, in which he is largely interested, is doing well, as also the Freeman and Franklin and other veins being worked in that immediate locality.

ORO BUTTE.—Late developments are encouraging. A tunnel was commenced to prospect the ground, and at a distance of 90 ft three well-defined veins of good ore were encountered, varying in width from three to five ft. In the largest of these veins, one man with a pick and gads can break down from three to four tons of ore per day. It mills about $35 a ton.

NEW MEXICO.

APACHE TAHOE.—*Grant County Herald*, Jan. 3: Chas. Davis is making preparations to erect a five-stamp mill, to be run by water power. He will purchase ore or do custom work, and as Apache Tahoe is conveniently located either for the Georgetown, Lone Mountain or Silver City mines, we have no doubt that the mill will be kept well supplied. It is Mr. Davis' intention to enlarge if his ore supply warrants, and the buildings will be erected with that in view.

UTAH.

BARBEE.—Silver Reef *Miner*, Jan. 3: The work of rebuilding the mill is progressing. The pan and settler frame are ready for the machinery, the battery is nearly completed, and the boiler and engine have been thoroughly overhauled and put in running condition. The machinery to arrive consists of a mortar, six pans, three settlers, smokestack, etc. If this machinery were on hand to-day, Superintendent W. T. Rich says he could have the mill completed and ready to start up by the 20th inst. He thinks everything will be in place by the 1st of February.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

LAWN SPRINKLER.—Corydon Chamberlain, Santa Rosa, Cal. No. 223,277. Dated Jan. 6, 1880. This invention is called the "Universal Lawn Sprinkler," and it consists in an attachment which may be screwed into the hose pips or nozzls, which attachment is provided with a nozzle and with a swinging arm having a conical circular plate or distrihuter, which disperses the current into spray after it leaves the end of the nozzle. The swinging arm carrying the distributer is moved at will, so that the distributer will produce all the effects produced by the various sprinklers in use. A suitable stand is provided also, upon which ths attachment may rest when used as a fountain, or when it is not desired to hold it in ths band. By the use of this device the whole percentage of the current of which the nozzle is capahle is obtained, since the current is not divided until after it leaves the nozzle. Complete control of the stream is maintained so as to producs seven or eight different effects—full stream, coarse spray, fine spray, etc. All the effects desired or obtained in the various sprinklers are produced in this one device. It cannot stop up with insects or other matter, since all that will flow through the hose and nozzle can pass out.

BALANCE SLIDE-VALVE.—David B. Kimmel, Idaho City, Boise Co., Idaho Territory. Dated Sept. 2, 1879. No. 219,161. This device relates to certain improvements in valves for steam and other engines; and it consists of a novel construction of a douhle slide-valve, having a vertical seat with ports so arranged upon opposite sides that they are controlled by the double valve. The two parts of this douhle valve are united by a frame, so as to move simultaneously, and be actuated hy a single valve stem. This valve is especially fitted for locomotive engines, in which the valves and ports are large, and the valves are subjected to great pressure and rapid motion.

REFRIGERATOR. — Thomas Guinean, Sacramento, Cal. Dated Sept. 2, 1879. No. 219,154. This invention relates to certain improvements in hotel and car refrigerators, and it consists in a novel combination of chambers, with surrounding air spaces or flues and connecting pipes, by which a body of cool air from the ice-receptacle is caused to circulate around one or more containing chambers, which are unconnected with the ice chamber or receptacle so that a body of cool dry air is maintained in these chambers.

HOTEL SERVER.—James G. Tait, Stockton, Cal. Dated Sept. 2, 1879. No. 219,183. The object of the inventor is to produce a convenient tray for the use of waiters in conveying dishes in hotels and restaurants; and it consists of a palette-shaped tray, having a slot at one side to fit the arm of the waiter, and legs, one of which serves as a handle by which to hold and steady the server. A drawer is placed heneath the server in which may be placed spoons, knives, forks, checks, etc.

AN attempt was made in London last Saturday to assassinate the priest of the Halton Garden Italian Church.

INDIANS are fighting the whites in Arizona, and troops have been dispatched to the latter's assistance.

WALLACE R. WHITE, charged with bribery in the Maine bnsiness, emphatically denies the whole story.

Mining and Opinions Concerning Metals Over two Centuries Ago.

CONTINUED FROM PAGE 41.

ths othsr, being with them a common trick, lest their work should he taken from them."

Law suits were common then, as now, upon such mines as the working proved to be rich. "Sir Lewis Bulmer, having brought a mine to great perfection, and getting great store of silver ore, had a controversie ahout the title, that grew to that height that he was forced to give over pursuing the labor, and so caused the workmen to throw in the works. Sir Richard Houghton set up a very profitable 'Mine of Allom,' and his competitors finding be could undersell their 'Allom,' a contention was raised against him about the sams mine, so that he was either compounded with, or otherwise forced to give it over; so that it is now quits left, to the loss of the nation in general and to many a poor man in particular, that got their living by working there."

Ingratitude among the mine owners for services rendered was, as now, not uncommon. One Walter Basley, 76 years of age, whose travels had been multifarious, "was brought down with some Londoners, that then had a patent for mines; * * * they at last desertsd the poor old man, whom I entertainsd for three-quarters of a year."

The minsrs were a migratory class: "For it is usual with the workmen, that if they can hear of another place whers they may find hetter wages, hoth to leave ths work and their masters."

An implicit confidence could not always be placed in the authors of that period: "Though in their writings there bs some things worthy of note, and may much better the understanding of such as be ignoran', if thsy take cars to try before they trust, and not to take everything for a truth that thsy may find in them."

Soms among them were belisvers in the "vegetability of metals"—that is, that metals grow in the earth as vegetables grow in the air. Hear Peter Martyr, Counsellor to ths Emperor Charles V., on this subject: "They have found by experience that the vsin of gold is a living tree, and that the same hy all ways spreadeth and springeth from the root, by the soft pores and passages of the earth, and ceaseth not until it discovereth itself unto the open air, at which time it showsth forth certain beautiful colors in the stead of flowers, round stones of golden earth in the stead of fruits, and their plates instead of leaves. * * * * They say that the root of the golden tree extendeth to the center of tbe earth and there taketh nourishment of increase, for the deeper that they dig they find the trunks thereof to be so much the greater, as far as they may follow it, for abundance of water springing in the mountains. Of the branches of this tree they find some as small as a thred, and others as big as a man's finger, according to the largeness or straightness of the rifts and clifts. They have sometimss cbanced upon whole caves, sustained and horne up as it were with golden pillars, and this, in the way by which the branches ascend, the which being filled with the substance of the trunk creeping from beneath the branch, maketh itself way by which it may pass out. It is oftentimes divided by encountering with some kind of hard stone, yet it is in other clifts nourished by the exhalations and virtue of the root."

Basilius writes: "In Hungary there is had everywhere gold-silver—that is, in it there is gold—which, in its color and ponderosity, is pure, hath lost nothing, and is still in its working quality; and if it had not been interrupted and digged up unseasonably, then the silver would have been turned into pure gold."

Those old writers were ever ready to apologize when they were at fault. Our friend Webster, in enumerating the writers to whose ideas of mines and minerals he confesses himself indebted, accidentally omitted the name of one of them, in consequnence of which he says: "I should have inserted Gabriel Fallopius with those of the first rank, but had forgot him, yet must now commend him to the studious as one that hath toyled sore by arguments to promote mineral knowledge."

They bad a sly way of saying good things, those writers of eld—brief, graphic, and like their peculiar ideas or metals, mystical and half hidden. Webster, while mentioning the favorahle indications of desirable mining locations, tells us, among other points, that it is good to find "some small twigs of a vein of ore, for then they think that there cannot but be greater store if they can find the right way to it." It can he readily perceived that the impediments to successful mining which those workers encountered have not yet been overcome, for the great obstacle in the way of reaching large hodies of ore at the present time is that our miners can not *"find the right way to them."*

From their descriptions it will he seen that the features attendant upon gold veins were the same as now. They considered the pale blue slates approaching to hornstone, in general characteristics, as a favorahle class of rocks in which to find gold veins. The softer "granite" rocks—the decomposed granitic series of the present day—were then, as now, held "good." Also the "grey or blewish stones, flints or slates, red or yellow clay or earth, or that appears of many colors," a description which would apply to the appearance of a majority of the gold veins in the slate rocks.

"Rich" veins worked they in their day, those good fathers of mining, and, in sooth, similar veins would in our times be entitled to the same appellation. "Also every vein of gold whereof an 100 pound weight doth contain more than three ouncss of gold is rich. All the rest of the veins of gold are to be esteemed as poor ones." This last quotation is from Georgius Agricola, who, as one of his contemporaries asserteth, was "a person of great experience and laboriousness;" and who, finding that much that was then known of mines and metals was likely to he lost, "determined to write of subterransous things that which hs had read or learned of, such as were skillful in metallick knowledge, or which he had seen in the mines."

Although the "divining rod" had in those earlier times many staunch adherents, thsre were not wanting men of sound sense who gave evidence against it. Thus, Paracelsus: "Therefore care is seduously to bs taken, that ye snffer not yourselves to be seduced by the divinations of uncertain arts, for thsy ars vain and frivolous, especially the Divinatory rods, which have deceived many miners. For if they once show anything rightly, thsy on the contrary deceive ten times." Kircherus speaketh thiswise: "Certainly I very oft making an experiment of this thing upon the metallick bodies of gold and silver, was always frustrated of my hops." Those who have in our day depended upon it have, like Kircherus, besn "very oft frustrated of their hope." On ths other side a Mr. Gabriel Platte, asserts that he used a divining rod which: "I carried up and down the mountains where lead grew, and before noon it guided ms to tbs orifice of a lead mine." I quote from Webster again, who doubtingly says: "The like story to this I have seen in an unnamed author, but shall hers omit it, because I know not of what credit he was." He closss a chapter upon the rod with still mors doubt: "I shall say nothing, but refer all to experimsnt; for some have believed too much, and some too littls."

Their idea of the spirit or soul of metals, runs through all their writings. Paracelsus gives gold a threefold character: "Gold in essencs is threefold; 1. celestial and loosed; 2. fluid; 3. corporeal." Rhumelius gives it credit for four attributes: "There are four sorts of gold: 1. *Astralish*, while it is yet green, crude, immature and imperfect; because the stars as yet have their influsnce and first operations therein. 2. *Mineralish*, is that very thing, which as yet doth stick in earth-ore. 3. *Metalish*, is tbat which being freed from its schleck and raw mineralish ore-stuff, and with great force of fire is driven forth of it, and tben may be called a pure and clear metal. 4. *Elementalish*, is any earth, mineral or stone, or ths like, wherein the spirit of gold doth lie hid, and may be drawn forth by the Spagyrick art." Paracelsus, in his covert way, thus slyly says to thoss who would obtain this volatile spirit: "Wbosoever therefore goeth about to get and separats the *primum ens* of every such like body, doth stand in need of mucb experience and knowledge in the Spagyric science."

The placer mines were the most profitable ones in those olden times. Strabo writes: "That gold is not only digged forth of the pits or mines, but also the rivsrs and torrents do afford a golden sand; and that by digging of pits, divers other artifices, and wasbing the sand, they get much gold; and that more did get gold this way than hy mining. And that amongst the sparks or crumbs of gold, there are sometimes found clods or masses of gold of the weight of half a pound, that need but little purifying."

Massive nuggets were frequently found then, for Peter Martyr says: "Inasmuch that there hath heen found round pieces of three hundred pound weight, and one of tbree thousand three hundred and ten pound weight, which was sent whole to the king." Oviedus confirmeth the notation of this last-mentioned "round piece": "And the greatest of all that was found to this day, weighed three thousand two hundred castellanes of gold." Mr. Boyle tells of "a mineral that was there digged up, wherein pieces of gold of the length and also of the bigness of a human finger, grew in the ore, as if they had been parts and branches of trees."

Kircher tells of a "mine of antimony that held in it some gold." Wormius states: "In 1644, the noble John Sigfridus being General Overseer of Metallic Matters, found a mine of gold, the ore being black and like talk, shining with frequent grains, which when he had, tried, an hundred weight of the ore yielded 38 marks of pure gold. Another vein in 1646 did, being purified, yield six drachms of pure gold, contained in one pound." Lazerus Erken, Chief Mine Master to Maximilian, the Emperor, informs us that "gold is found in a white stone like marble (the Germans call it quartz); as also in a blue and yellow hornstone, likewise in a blue slate."

A question which has been revived in our day, and is still mooted without reaching a solution, was over two centuries ago definitely settled hy this old writer, Webster, whom we have quoted heretofore. Even in his time it was a matter of dehate as to the location of the Ophir from whence Solomon obtained so much gold. After devoting some pages to the subject, he says he will "lay down tbat proof that may demonstrate that the land of Ophir or Uphaz was the two Peru's now known to Europe. For that text is so plain, that no reasoning can be ahle to overthrow it. For it is said in the text: *'And the gold was the gold of Peruaim.'* And all men know that the Hebrews put *a-im* in the dual nnmber, as *Peru* heing the singular number, when *a-im* is added to it in the dual it makes *Peruaim.*" After this let this vexed question he at rest; for, has he not written that

"no reasoning can he able to overthrow it"!

A characteristic of gold mining existed in ancient times that is peculiar also to the present age. Diordorus Sicnlus is my authority for this assertion: "In the borders nf Egypt, that joyn to Ethiopia and Arabia, there are places very fertile of metals; forth of which, with *much labor and expense*, gold is drawn." The same author further describes the process of mining the ore from the veins of quartz, which was then termed "marble:" "That almost infinite thousands of men do dig forth, with iron instruments, the more soft rock, and which is broken with indifferent labor. He that discoverth the veius of gold, goeth before the workmen, showing what places they are to dig. They cleave the strong marble, being shewed, by the strength of strong bodies, not hy art, but by great force with iron wedges. But they drivo shafts or passages not straight, but that way which nature leadeth, hy the gold in the shiuing marble. But when hy reason of the divers hendings, and turnings, they are darkened in their passages, the workmen carrying lights before them, the rocks, hy great force heing cut in pieces, they carry up and cast upon the ground. Others cut them so casten into very small pieces, others carry them away. The pieces taken from these workmen, heing eut to a certain measure, they heat in stone vessels with a pestle, or hammer of iron, unto the smallness of millet seeds. They then heing cast into mills, are grinded unto the very fineness of meal. Then the workmen taking it ground, do put it upon broad tables, a little declining, and agaiu heat or rub the marhle, water being cast upon it. By that means, the earth heing washed away, the gold hy its gravity doth remain upon the tables. This they often iterating, they rub the gold with their hands. Then with thin and porous spongos, they press forth the soft earth, until it he made like nnto golden sand. Lastly, other workmen do put it hy weight and measure into eartheu pots; and do superadd in a certain measure lead, seaweed or tange, and bran of barley. These things compounded in a certain proportion, they diligently leme or dauh up the pots with clay, or lute. Furthermore, heing decocted five whole days and nights in a furnace, pure gold is only found in the vessel, the other things heing wasted, the former weight heing little diminished." Webster, from whose work is copied the above translation, continues: "I have the rather delivered this at large, because it is a very remarkable passage, and perhaps not taken notice of hy many readers, and may he of some considerable use to an ingenious mineralist." The buddle which is used in the Cornish mines had its counterpart in the workings hnndreds of years ago.

From the foregoing extracts an idea may he gained of the views held more than two centuries ago, in regard to the nature of metals. Many of the chemical properties of metallic salts were understood practically, hut theoretically they were not comprehended; wild and visionary views heing entertained concerning them. Their aim was to discover the essence or vital principle of each metal, which they helieved to exist, and hy the aid of which all metals of a lower grade could be raised or transmuted to the more valuable metals above them in the scale. But in the search for the unknown, in the vain desire to materialize the ideal, much valuable knowledge was obtained, sufficiently so to form that heautiful process of practical chemistry which now stands forth as one of the noblest evidences of the power and strength of the human intellect.

News in Brief.

The marriage of General Garibaldi has heen annulled.

Parnell spoke at a meeting in Philadelphia last Saturday.

A new opera house at Napa was dedicated January 9th.

Comanches from Texas are depredating in New Mexico.

The delegation of Ute Indians have arrived in Washington.

Dr. William Budd, the eminent London physician, is dead.

The St. Louis shoemakers demand an increase of 10% in their wages.

In county Galway, Ireland, process-serving is heing violently resisted.

The life insurance fund of the Pacific Stock Exchange has heen aholished.

Bogart, the defaulting treasurer of the New York Produce Exchange, is dead.

A serious strike is in progress among the miners in the Basin of the Loire, France.

In the Kanawha valley, W. V., the miners are in a state hordering upon insurrection.

Unemployed laborers at Cork, Ireland, plundered meat and bread shops Saturday last.

The death of Lieut. Gen. Skoheloff, Russian Inspector General of Cavalry, is announced.

The convention of the National Greenback Labor party will he held in Chicago June 9th.

Beecher addressed a meeting in New York recently in hehalf of the sufferers in Ireland.

Great excitement still exists in Maine, two State Governments now heing in existence.

Earthquakes occurred January 9th at several points in the southern part of the State.

Much sickness prevails among the British troops in Afghanistan, principally pneumonia.

At Manuwaki, Canada, a man named Brishes chopped his partner to pieces and escaped.

An unsuccessful attempt was made in New York recently to roh the grave of Count Joannes.

The True Healing Art.

We have received a copy of a lecture just published by Dr. DeWitt Clinton Moore on "The Science of Health Conservation and the True Healing Art, Hygeio-Therapy." The lecture is devoted to "explaining the first principles of Hygienic Medication, or a true Medical Science, and exposing the fundamental fallacies of all drug systems." The lecture fills a closely printed pamphlet of 12 pages, and is written in a very vigorous and straightforward style. It can hardly fail to hold the reader's attention to the close, although its unyielding rebuttal of most accepted ideas of medication will awaken opposition in many minds. The subject advanced and ably treated is one of the greatest importance, and certainly should be considered by all. We have not space to review the argument built up by the author. Indeed, this is not necessary, as the pamphlet is for free circulation, and all may obtain it by sending a three-cent stamp to the author at No. 8 Ellis street, San Francisco. It may be said, however, that the system advocated is one in which no drugs are used except to kill abnormal growths or remove offending material, and it is maintained that "as health results from a right use and relation of things and conditions (affecting life), disease must be caused by abuse or misrelation of them; hence, the true healing art consists in returning the patient to obedience to these laws—by placing him in true relation to his environment—in removing the causes of disease and supplying the best conditions of health."

OUR AGENTS.

Our Friends can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. Tharp—San Francisco.
B. W. Crowell—California.
A. C. Knox—Pacific Coast.
S. V. Blakeslee.—California.
O. W. McGrew.—Santa Clara county.
J. B. Bachelder.—Shasta County, Cal.
James Rogers—Oregon and Washington Ter.
Thos. H. Manning—Nevada, Idaho and Montana Ter.
Capt. W. H. Seamens—Arizona.
M. P. Owen—Santa Cruz County.
H. E. Hallett—Los Angeles County.
Perley P. Kilbourne—Sacramento County.
M. B. Starr—Contra Costa county.
F. M. Varden—Alameda Co., Cal.
C. A. McMahon—Butte Co., Cal.
W. B. Turner—California.
J. W. A. Wright—Merced, Tulare, Kern and Fresno counties.

We are under obligations to Messrs. Dewey & Co., S. F., for a copy of the "Pacific Rural Handbook," by Charles H. Shinn. The book embraces 120 original pages, and contains a series of brief and practical essays and notes on the culture of trees and shrubs, adapted to the Pacific Coast; also hints on farm and household economy. It contains valuable suggestions on laying out grounds, improving soil, irrigation, wind-breaks and hedges, fruit trees and small fruits, shade trees, shrubs, the vegetable garden, flower garden and lawn, seeds and seed planting, cuttings, etc. The book is substantially bound in cloth, and sent postpaid for $1. Address Dewey & Co., No. 202 Sansome St., San Francisco.—*Kern County Gazette.*

Bound Volumes of the Press.—We have a few sets of the back files of the Mining and Scientific Press which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce, and valuable for future refereuce and library use.

A Cylinder Pressman

Of good experience wants a situation in a S. F. or interior office. Understands running an engine. For a steady situation will accept moderate wages. Address "No. 2," this office.

An Engineer

Wants a situation to run a stationary engine in the city or country. Will accept a modorato salary. Address "No. 1," this office.

Fresh attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

Sample Copies.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

Extra Copies can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Atlanta Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, West Tintic Mining District, Juan County, Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the Second day of January, 1880, an assessment (No. 1) of Five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, No. 420 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Fifth (5th) day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Friday, the Twenty-Fourth (24th) day of February, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

A. F. McGREW, Secretary.

Office—Room 7, No 420 Montgomery street, San Francisco, California.

Butte Hydraulic Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 2) two levied on the Thirty-first day of October, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
E Poirson	13	2½	$25 00
L Lapierre	22	2½	25 00
H Marceoux	24	2½	25 00
J B Lussier	25	2½	25 00
John Britt	26	2½	25 00
Geo W Deitzler	37	5	50 00
N Desautelle	41	2½	25 00
Jos Lucier	42	2½	25 00
N Goldtree	43	7½	75 00
Geo Moreau	44	5	50 00

A L Lengfeld	5	5	50 00
L L Dennery	6	5	50 00
W E Lutz	7	5	50 00
Geo. H. Powers	11	5	50 00

And in accordance with law and an order of the Board of Directors made on the 31st day of October, 1879, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the company, room 3, No. 220 Sansome street, San Francisco California, on Monday, the 22nd day of December, 1879 at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

L. L. DENNERY, Secretary.

Office, room 3, No. 220 Sansome St., San Francisco, Cal.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock of the Butte Hydraulic Mining Company is postponed to the Fifth day of January, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock is postponed to the second day of February, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

San Francisco, Cal., January 3d, 1879.

Gover Mining and Milling Company.—

Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given that at a meeting of the Directors held on the 24th day of December, 1879, an assessment (No. 40) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the second day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the First day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale

W. O. WILSON, Secretary.

Office—402 Front street, room 8, San Francisco, California.

Mariposa Land and Mining Company of

California.—Location of principal place of business, San Francisco, California. Location of works, Mariposa County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 10th day of December, 1879, an assessment (No. 17) of Fifty (50) cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. currency to the Secretary, at the office of the company, room 33, Nevada block, No 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 10th day of January, 1880, will be delinquent and advertised for sale at public auction; and unless payment is made before will be sold on the 2d day of February, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

LEANDER LEAVITT, Secretary.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

A. S. HALLIDIE,

Office, No. 6 California Street,

SAN FRANCISCO.

Manufacturer and dealer in all kinds of

Iron and Steel Wire Rope,

Flat and Round, for Mining, Shipping, Hoisting and General Purposes.

Having the most complete and extensive Wire Rope Works in the United States, I am prepared to manufacture Wire Rope and Cables of any length or size at short notice, and guarantee the quality and workmanship equal to any made at home or abroad.

Iron, Steel and Galvanized Wire

Of all sizes on hand or made to order.

Barbed Fence Wire.

Sole Proprietor of

Hallidie's Endless Ropeway,

For the Transportation of Ores, Etc.

VOLUME XL Number 4.

Lodes and Ore Deposits.

Mode of Origin of the Great Flat Lode.

In our issue of December 27, 1879, we gave some extracts from a paper by C. Le Neve Foster "On the Great Flat Lode south of Redruth and Camborne, and on some other tin deposits formed by the alteration of granite." In that part of the paper treated in that number of the PRESS, we gave some engravings showing sections of the lode in question, and we have now to consider the probable mode of origin of these deposits of tin. These distinctive features are:

1st. The invariable presence of a small leader, generally only a few inches wide, apparently occupying the space due to the shifting of the two sides of a comparatively flattish fissure, and filled partly mechanically, partly chemically.

2d. A lode or mass of stanniferous schorl rock, containing 1% to 3% of cassiterite, from 4 to 15 feet in width, either above, below, or on both sides of the leader. The tin is distributed in little grains in the rock, or in strings or minute veins. We believe that the fact of the lodes themselves consisting of *schorl rock* is a point which has never before been made known.

3d. Schorl rock poor in tin ore (locally called *capel*, *grayback*, *black granite*), separating the lode from the granite, and schorl rock, with its constituent minerals arranged in layers, also called *capel*, separating the lode from the killas.

4th. Gradual passage of the schorl rock (capel) into lode on one side and into granite or killas on the other; in other words, absence of any *wall* between the capel and the lode, or between the capel and the enclosing rocks.

All these facts point, in Mr. Foster's opinion, to the idea that the lode and capel are merely altered rocks, the fissure now occupied by the leader having served to bring up vapors or solutions capable of entirely changing the rock on both sides of it. The microscopical examination affords confirmatory evidence that the compact blue stanniferous schorl rock was once granite.

Alteration of Granite in other Districts.

That granite can be altered into schorl rock is a fact that can scarcely be questioned. Every china-clay pit affords evidence of the fact. You constantly find little veins of quartz, or quartz and tin ore, bounded on each side by granular schorl rock, which is followed by granite more or less decomposed. The sharp walls of the quartz veins on the sides of the original fissures, and the absence of such walls between the granite and the schorl rock, is what would be expected if the altering solutions gradually soaked in from the sides. Sometimes the schorl rock itself bears plain marks of its origin, as it contains numerous pseudomorphs of quartz after orthoclase.

It must not be supposed that schorl rock is the only form of altered granite. The conversion of granite into "Greisen" is not uncommon, and Prof. Von Cotta has given ample proof that the fine grained *Zwittergestein* has also been derived from the same rock.

In the parish of Wendron, Cornwall, are several remarkable tin deposits deserving special mention in this connection.

The Balmynheer mine is remarkable for presenting a large, irregular mass of stanniferous rock, the mode of occurrence of which will be seen from the accompanying section (Fig. 1.) In this, *G, G*, is ordinary granite, *B, B*, is the tin-bearing rock, in the form of a mass from 30 to 50 feet thick and following the *slide*, *A, A*, six inches thick is a vein of white clay with a little quartz and mica. Much of the tin rock is full of little cavities and where this honeycombed structure is apparent the stone is sure to be rich in tin. Between the tin-deposit and the underlying granite there is no regular plane of separation; on the contrary there is a gradual passage—the rock becomes less cellular, feldspar crystals appear spotted with chlorite and finally you come to clean granite. Occasionally there is a little tin rock above the slide or the granite may contain iron pyrites.

The Lovell mine is an example of a still more curious deposit, there being two so-called lodes or veins, the two lodes finally uniting. At the south lode I take a section as I saw it at 30 fathom level (Fig. 2).

In the engraving, *A A*, is ordinary granite, *B B*, is the so-called *cab*, composed of quartz, mica, gilbertits, chlorite, iron pyrites, copper pyrites, and a little schorl. It is usually from 6 to 12 inches thick, and is sometimes found on both sides of the lode. *C C*, is the lode itself, a compact, dark-colored mixture of quartz, gilbertite, mica, zincblende, chlorite, iron pyrites, and a little copper pyrites, fluor and tin stone; of the latter the rock carries two and a half per cent. The most remarkable point with regard to this lode is the occurrence of numerous pseudomorphs of quartz after orthoclase, many an inch long by one-quarter inch wide. And they show out very plainly in the dark ground formed by blende and chlorite. Some of the pseudomorphs contain small grains of cassiterite. The lode is traversed by numerous joints, which are mere planes of division in the rock; the principal ones dip and strike at the same angle as the lode itself. When, however, a joint diverges it carries "lody stuff" with it. Thus, if a joint, *E F*, goes off from the main joint, *C D* (as shown in plan, Fig. 3) a little tin stuff will be found following it for a short distance into the granite. These so-called lodes or masses of tin-bearing rock, do not run continuously from one end of the mine to the other, but only occur in bunches here and there; and when these gradually come to an end on all sides, the lode becomes a mere joint in the clean granite.

The South Wendron mine, adjoining the

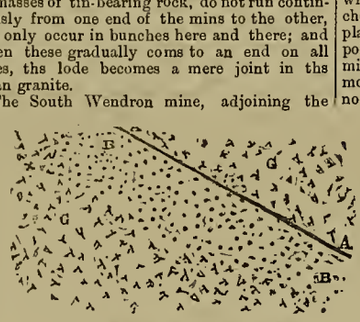

Fig. 1. Section at Balmynheer.

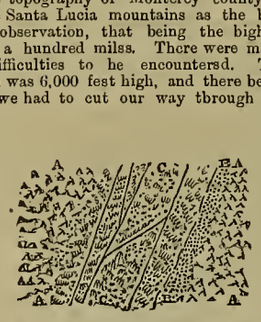

Fig. 2. Section at Lovell Mine.

Fig. 3. Plan of Lode at Lovell Mine.

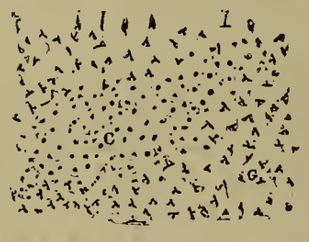

Fig. 4. Plan at South Wendron Mine.

Lovell on the southeast, is worked upon a *pipe* of tin-bearing rock of a somewhat remarkable character (Fig. 4.) It may be described as a very irregular cylindroid of stanniferous rock, merging gradually on all sides into granite, with its axis dipping at an angle of 49° in a direction N. 25° W. The longer axis of the oval section of the *pipe* is from 20 to 60 feet in length, whilst the shorter is about 10 feet. The mass consists of quartz, mica, gilbertite, a little iron pyrites and tin stone, and is traversed by a few irregular joints. The stuff is usually cavernous or honeycombed, and in the little cavities fine acicular crystals of tourmaline may often be detected. The southern part of the *pipe* is sometimes very granitic in appearance, and consists of pink orthoclase crystals imbedded in a mass of quartz, chlorite, mica, iron pyrites, copper pyrites, fluor and tin ore.

The characteristics of these three deposits may be summed up in a very few words: They are masses of stanniferous rock passing gradually into the surrounding granite. The fact of the passage and the presence of the pseudomorphs justify us in concluding that the so-called lode at the Lovell mine was once granite; and if this is admitted, we can have no hesitation in affirming that the Balmynheer and South Wendron deposits were formed by the alteration of the same rock.

The conclusions drawn from these facts as bearing on the question of the proper definition of the term lode or mineral vein, we shall give in our next number.

The Solar Eclipse.

Observations of the Coast Survey Party.

At the meeting of the California Academy of Sciences on Monday evening, Prof. Geo. Davidson, of the U. S. Coast Survey, said that, as Superintendent of the Coast and Geodetic Survey, had given him permission to communicate to the Academy the general facts observed during the late solar eclipse. Then, with the aid of the blackboard, he described the points of interest in a very lucid manner. He said:

In the late eclipse the cone of shadow was so small, from the apparent diameter of the sun and moon being so nearly the same—the latter exceeding the former by only the two-hundredth part, that it made it hardly worth the while of astronomers to come here from different places to view it, especially as it took place so late in the afternoon. Being well acquainted with the topography of Monterey county, I chose the Santa Lucia mountains as the best place of observation, that being the highest point for a hundred miles. There were many minor difficulties to be encountered. The mountain was 6,000 feet high, and there being no trail, we had to cut our way through the

exhibited themselves. On account of the slight apparent diameter of the moon, the crusts became remarkably sharp. As the moon advanced, upon its edge became visible the lunar mountains. The darkness above the disk of the moon was less than the darkness of the moon on the sun. Venus and Mercury have both been seen projected on the corona before their transits, and it has been supposed possible to see the dark body of the moon before it touches the sun. None of us saw it, however, and I doubt if any authority has.

My instrument was so arranged as to exclude all but one-tenth of the light and heat rays. The approach can be detected by spectroscopic methods before it quite touches, but not as a dark body. As the two disks became concentric, the crescent was moderately prolonged, because the diameter of the moon was apparently only 1-200th greater than that of the sun. At that time the sun was passing into some cirrus clouds. I was somewhat surprised at the prolongation of the segment. As it became narrow the phenomenon of Baily's Beads, a series of bright points of the sun hanging on the edge of the moon, caused by the irregularity of the waves of light from atmospheric vibration, was possible. This phenomenon was not visible owing to the clear atmosphere, but the line of light was broken into dots and dashes, like the Morse alphabet. And when one point of light disappeared it did not reappear, as in Baily's Beads, but was gone for good. Thirty seconds is a very short time, unless you are hanged by the neck. That was all the time we had, however. Each one of us attended to his assigned duty. I was seeking for an intra-Mercurial planet, and had one chance in a million. I had prepared a chart, with all the stars down to the seventh magnitude, and hoped to locate any unknown star by the configuration of those about it. I was satisfied beforehand, however, that the sky was too bright and that the cone of shade was too bright from a sort of re-illumination.

When the shadow came over the ocean we saw a shade of so light a brown that it was a disappointment to me, knowing that an intra-Mercurial planet would probably be invisible. There are four sketches of the corona made by our party, however, more consistent in their outlines than those by many more skilled observers with much more time. It is impossible to describe the magnificence of the sight that the eclipse presented. Huge masses of red flames burst out above the upper surface of the sun one-twelfth or one-fifteenth of its entire diameter in size, from 40,000 to 50,000 miles in height. The lower limb of the sun produced a broken, jagged line of rose-colored intense flame, extending around a third of the sun's circumference, above the apparent disc of the moon, and covering millions of miles in area. The flames were visible for one or two seconds after the disappearance of the sun, a rather unusual phenomenon. After the re-appearance of the sun a curious thing occurred showing the effect of atmospheric causes. The atmosphere became disturbed and in watching the end of the eclipse the limbs of the sun and moon were remarkably disturbed. The smaller telescopes lost the point of contact. As the moon went out of the sun's disc, two curved, wavy lines appeared in black and red. Had the atmospheric vibration occurred at totality we should have had an exhibition from this cause of Baily's Beads. The photosphere or disc of the sun during totality was covered with the phenomena known as "rice grains." The mottlings were remarkably well portrayed. Among these were larger and more crooked lines of bright light of irregular shades and forms. These were the aspect of the masses of flame. The theories of various astronomers and physicists were referred to, and the speaker seemed to favor that in which the greater part of the solar volume was gaseous, highly condensed, because it would best account for the supply of heat which the sun was constantly radiating into space. In the corona as seen by the spectroscope, the green line called "1474," for which we have no element on earth, and the helium line preliminarily so called, were exhibited.

chemical. In the instructions for astronomers issued in 1878 for the eclipse of 1879, it was especially mentioned that the English and American almanacs differed so that the estimated paths of totality differed three miles in location. I was desirous, though the arrangements could not be made, of having the north, south and central points determined by different observers at different points, and thereby rectify minute errors that might exist in the nautical almanac. To meet the requirements as well as possible our party was equipped with a large equatorial of 6½ inch objective, one of 3 inches, two of 2⅞, and one of 2¼, all good glasses of high power and definition. These last qualities, as well as the quiet atmosphere and the high elevation which we sought to obtain, are necessary in order that the first and last points of contact may be accurately observed. The beginning all along the coast was similar to what you saw here.

The moon left the sun at a point about 16 degrees from the vertical on the left. By the high power and large aperture of my glass I was enabled to see the first movement on the limbs several seconds ahead of the others.

Both disks were real and not spurious. Spurious disks arise from the undulations of the atmosphere, occasioned by unequal refraction, and in that case the body of the sun or moon will not only appear too large, but there will be no well-defined point of contact at any phase. As the moon advanced we saw its contact with the sun's spots in three different groups. As totality advanced, several peculiar phenomena

Spruce Mountain Mines.

Answers to Important Inquiries.

EDITORS PRESS:—I would like, through the medium of your valuable and highly appreciated columns, permission and space to answer the several questions recently received from different parties by letters of inquiry regarding the principal mines in this district; its location and facilities for working the ore. Knowing your ability and willingness to aid and assist in the development of any legitimate mining enterprise, I believe that such permission will be granted; and I will consequently proceed:

1. This mountain is 35 miles southerly from Wells, a town 215 miles west of Ogden, on the Central Pacific railroad. The wagon road from Wells to Spruce mountain is of good and easy grade, over which heavy freight teams are frequently passing on their way to Cherry Creek, Shelhorn, Ward and other points south of Sprucemont. The mountain is surrounded by fertile valleys, in which stock raising and farming are successfully conducted. This mountain is sufficiently heavily timbered to last, for mining and building purposes, for many years. The adjacent foothills are heavily timbered with nut-pine, the best wood for making coal. There is plenty of water for all practical purposes, and nothing lacking that nature can provide to make it the equal of Eureka or the best camp in the west.

I will only give descriptions of a few of the principal mines, which I think will be sufficient to satisfy those anxious inquirers for mining property, in which they can be sure of making a safe, legitimate and remunerative investment.

The Mines.

I will first describe the Juniper. It is situated on a spur of the mountain running from the summit to the northeast, and is developed by cut, tunnel, incline and shaft to a depth of 150 feet. For the last 50 feet, it shows a very large body of good ore. The size of the ledge is not known, but it is evidently a "mammoth" mine. The ground is patented. A tunnel has been started to cut the ledge, and is in 300 feet, but has not reached the point where it should strike it, at a depth of 250 feet; but it will probably be driven ahead ere long to that point, where the owners expect to open a bonanza.

The Black Forest group of mines are situated a quarter of a mile northeast from the Juniper. There are four locations adjoining, of which the Black Forest is the principal. It is developed by three tunnels run into the mountain at different levels, each tunnel cutting the ledge and showing large bodies of high grade, free smelting ore. The upper tunnel is in about 80 feet, and has cut two large chimneys of ore. The upper and middle tunnels are connected by an incline run down on the first chimney. The middle tunnel is in about 225 feet, and has cut three large chimneys of ore. It is connected with the lower tunnel by an incline run down by the side of the third chimney. The lower tunnel is in about 275 feet, and cuts the vein at a depth of about 300 feet on the dip from the top of the ledge. From the level of the lower tunnel there have been two inclines sunk on the vein—one 30 and the other about 50 feet—both of which show the largest and cleanest body of ore in the mine. The prospects for further developments are exceedingly flattering. There has been no stoping nor drifting done in the mine for the purpose of extracting ore, only such as lies in the regular course of the tunnels and inclines having been taken out. It is estimated by good judges that there are from 600 to 700 tons of splendid ore on the dump, and from 8,000 to 10,000 tons in sight, which can be placed on the dump at a very small expense. The ore is calculated to average 40% lead and from 40 to 50 ounces in silver per ton. I can here give you a better idea of the facilities for and the expense of working the ore in this mine by figures obtained from reliable men who have had many years of experience in the business elsewhere:

1. A 30-ton furnace can be built and arranged ready to run for about $10,000.

2. Six coal kilns, 17 feet in diameter by 18 feet high, will furnish sufficient coal for the furnace. Two men are all that are required to attend to them; said kilns can be built for $5,000.

3. Wood can be contracted for at from $4 to $5 per cord, and one cord will yield from 45 to 50 bushels of coal—the cost of which will not exceed 12½ cents per bushel. Seven hundred and fifty bushels of coal are sufficient to smelt 30 tons of ore.

4. The ore in the Black Forest mine can be extracted and placed on the dump for $1.50 per ton, and hauled from dump to furnace for 50 cents per ton.

5. The cost of smelting will not exceed $7 per ton.

6. Three tons of this ore will yield one ton of bullion. The freight on bullion from furnace to railroad (Wells) will cost $8 per ton, and from Wells to New York market $40.50 per ton—making freight $48.50.

7. For the convenience of inquirers and readers of this article, I will arrange in condensed form (hereafter) the figures showing the expense of converting 10,000 tons of this ore into cash; also the net profit resulting therefrom.

Great care has been taken to obtain the above figures from practical and reliable men, such as John McVicker, of Salt Lake City, and many other reliable assayers; also Mr. Frantz Jung, of the Germania Smelting Company, Utah, Mr. Remley, of Utah, a practical coal-kiln builder and burner, and from the different general freight agents of the railroad companies from the Central Pacific railroad to New York city.

I believe that the calculations and figures given below can be worked up to and the result, as shown by the figures, fully demonstrated:

Value of lead in 3,333⅓ tons of bullion at 5½ cents per lb., in New York market	$366,666.66
Value of silver in bullion, reckoning 40 ozs. per ton of ore, or 120 ozs. per ton of bullion, at $1.12 per oz.	448,000.00
Total	$814,666.66
Cost of furnace, machinery, etc.	$10,000.00
Cost of 6 coal kilns	5,000.00
Cost of ore house, track, cars, etc.	3,000.00
Cost of mining, hauling and smelting 10,000 tons	90,000.00
Freight on 3,333⅓ tons of bullion from furnace to New York market	161,666.66
Total	$269,666.66
By net profit in the business	545,000.00
	$814,666.66

I will here add that, in addition to the above-described mines, there are numerous prospects that show exceedingly well for the amount of work done on them. I am confident that if a good company, using sound judgment, with the necessary qualifications, such as capital, energy and honor (a part of which, however, may be a novel element to some who have been in this camp), would buy the property, they can, within 60 days from date of beginning, declare a dividend of over $30,000 from the net profits, and continue so doing regularly every 30 days thereafter. I hope that the inquirere will find in the above the information desired.

OLD FORTY-NINER.

Wells, Elko Co., Nev., Jan. 14, 1880.

Northeastern Arizona.

EDITORS PRESS:—While general attention is being directed to the central and southern portions of the Territory of Arizona, little or nothing is said about Mohave county, comprising the northeastern portion of the Territory. This immense county is about 250 miles long, with an average width of 100 miles. Its resources are limited almost entirely to mineral products, gold, silver, lead, antimony, copper and iron ore being found in great abundance in all parts of the county. Its agricultural products are decidedly limited, only two small portions of the county being in any way suitable for farming, viz.: Along the Sandy creek, at the southern end of the county, and along the river bottoms of the Colorado, which bounds the county on the north.

The land along the Sandy suitable for farming consists of a strip about nine miles long, varying in width from one-half to three miles; this produces every year large crops of barley, barley hay and alfalfa, which finds a ready market at Mineral Park, Signal, Cedar and McCracken and other mining camps in the county. Considerable flour and barley for Mineral Park, comes by Colorado river steamers from California. The agricultural lands on the Colorado consist of a few scattered ranches, devoted principally to stock raising, though some barley and hay is raised, most of which is consumed at Fort Mohave, on the river. Large quantities of watermelons are raised every summer on the rich river bottoms—melons that cannot be excelled anywhere for size and flavor. There are also a few scattered ranches, consisting of a few acres each at the springs and stage stations, devoted principally to vegetable raising, but these like the springs and stations are very few and far between.

It is to the

Great Mineral Resources of Mohave County

That I desire principally to call attention. There is a wealth of mineral here in this almost unknown part of the world that is destined ere long to throw into the shade all past discoveries in the Territory, not excepting even the great Tombstone district. The principal mining district of the county is situated in and around Mineral Park. Within a radius of 20 miles are the mining districts of Cerbat, the former county seat, Stockton, Hualpai Mountain and Chloride. Mineral Park, the present county seat, has a comfortable court-house, recently erected at a cost of $6,000, two large stores, post-office, livery stable, drug store, three saloons, two butcher shops, one shoemaker, two restaurants, an assay office, wagon and blacksmith shop, one doctor and three lawyers. Also one first-class five-stamp quartz mill, owned by Messrs. Breon & Spear, which has the reputation of being the best mill in the Territory of its size, and also of working ores to a higher percentage. Messrs. Breon & Spear are the wealthiest firm in the county, owning the mill, principal store, Keystone and Ithaca mines at Mineral Park, besides various other mines in other parts of the county, as well as a store at Fort Mohave.

The Keystone mine is down 260 feet, has steam hoisting works, and employs from 5 to 30 men. The ore is rich in antimonial silver, assaying from $100 to $1,500 per ton, averaging probably $300. This is generally considered the leading mine in the camp, but its title is disputed by the Lone Star, owned by W. F. Grounds. This mine is down 200 feet, and differs from most of the mines about here in that its ore carries a very large percentage of gold. This may be called the "specimen" mine of the county, furnishing any quantity of specimens rich in wire, horn, native and ruby silver; average ore from the 200 level of this mine will assay from $200 to $1,000 in silver and $100 in gold. This valuable mine, together with the "Setting Sun," a mine with an eight-foot ledge averaging $100 to the ton, has lately been sold to Messrs. Pinkham, of San Francisco, and Carroll, of Sacramento, who propose to erect immediately a ten-stamp mill, steam hoisting works, and to thoroughly prospect the two mines.

Another good mine is the Fairfield, formerly owned by Hon. W. H. Hardy, who is the present Superintendent, and sold by him last fall to a wealthy New York company. The company are running a tunnel 900 feet into the mountain to tap the main shaft of the mine at a depth of 250 feet. Pending the completion of the tunnel, about 250 feet of which remains to be finished, work on the mine is suspended. When the tunnel is finished the company propose to put a large force of men on the mine, and also to erect a ten-stamp mill and steam hoisting works. Great results may be expected from this mine, which has a brilliant future before it.

The Other Principal Mines

Around Mineral Park are the Ithaca, Setting Sun, Blue Boy, Starke and Ewing, Old Mohave, Cincinnati, and a thousand others on which more or less work has been done, according to the means of the locators. Suffice it to say that the whole mountain range is honey-combed with tunnels and shafts, and ore that will not assay $150 to the ton is not considered worth working. All that is wanted to make Mineral Park a second Leadville or Bodie, is a few live capitalists to develop our mines, the present owners not having the means to do so. Among other companies about to operate here is the Cerbat mill and mining company, owning about 15 mines in and around Cerbat; they also have a five-stamp mill in course of erection at the Gold Bar mine, which, as its name implies, is a gold mine. Specimens from this mine show free gold in large quantities. At Cerbat is the Connor mine and mill, owned by John Barry. This mill is doing good work on ore from the mine, which is one of the best in the county. At Chloride is a smelting furnace, formerly owned by Temple & Workman, of Los Angeles. This property has recently changed hands, and the new owners are now engaged in putting it in running order. At Stockton are several rich mines, notably, the I. X. L. and Infallible, at present houded to a company of Oakland capitalists who propose to erect a mill, etc.

All of These Outside Camps

Are dependent on Mineral Park for supplies, being supplied by pack-trains, etc. At Hackberry, 35 miles south of Mineral Park, is the property of the Hackberry mill and mining company, consisting of the Hackberry mine and a ten-stamp mill. This mine is down 450 feet, furnishing $400 ore enough to keep the mill running. This splendid property is now lying idle, owing to the company having become involved in litigation, caused by extravagant salaries to useless officials, offices in San Francisco, etc., together with general reckless management. At Hualpai Mountain, 25 miles from Mineral Park, is the celebrated American Flag mine. This mine was bought 12 months ago by six Cornishmen, for $25,000. Since then they have extracted ore enough to pay for the mine, besides doing over 700 feet of tunneling. Third-class ore from this mine assays $150 silver. Second and third-class ore is milled at Breon & Spear's mill, and first-class ore shipped to San Francisco. Here also is the celebrated Bill Deen mine, also involved in litigation. In the southern part of the county is the great McCracken mine, furnishing any amount of low-grade ore, keeping a 20-stamp mill constantly running. At Signal there is a 10-stamp mill; also one at Cedar, recently built by a New York company.

The assessment roll of this large county foots up over $840,000, and the great register shows a list of 345 voters, thus making this county, in proportion to its population, one of, if not the richest counties on the Pacific coast. Miners' wages are $4 a day; mill men, $5 and $6; engineers, $5; carpenters, $7; board, $10 and $11 per week. Provisions and clothing are very high; barley, from 4 to 12 cents per pound, according to season; flour, from $10 to $12 per 100 pounds; bacon, 30 cents a pound; eggs, 75 cents a dozen, canned fruit and meats, 75 cents per can; lumber, $140 per 1,000, and everything else in proportion. Meat is high, being 15 to 20 cents per pound; no mutton in the county. Any further information in regard to this part of the territory will be cheerfully furnished by the writer, whose name will be furnished by the Editor. * * *

Mineral Park, Mohave County, A. T.

Tem Pahute District.

EDITORS PRESS:—The district of Tem Pahute is situated in the western portion of Lincoln county, 200 miles east of south from Eureka, and about 100 miles almost due east from Tyho, in an isolated mountain, a broken continuation of the White Pine range, and evidently a segregation from that portion of the range known as the Pahranagat mountain, that rises skyward a few miles to the east. The Tem Pahute mountain is some ten miles in length by four in width, of an average altitude of from 6,000 to 7,000 feet. The ore-bearing belt is of immense width, measuring 1,000 feet at the southern, and widening to one-half mile at the northern end, with a general trend of north and south, and an easterly dip of from 30 to 70 degrees. The formation is, on the eastern or banging wall of the belt, a lime shale, like that at the Eureka Consolidated, and also at the Raymond & Ely at Pioche.

The western or foot wall of the belt consists of an immense reef of quartzite. Below this again, and appearing at intervals across the valley, is a white and red sandstone, where the geologist would find some very interesting erosions. The mountain is covered with the scrub pine and cedar peculiar to the country, useful for firewood and mining timbers, but for no other purpose. There is an abundance of feed in the foothills and valleys, of the nutritious grasses of the country—bunch-grass, sand-grass, etc. Water has heretofore been considered the grand desideratum, and the lack of it the great drawback; but of late, developments have demonstrated that an abundance of the aqueous fluid exists in the mountain eight miles west, several miner's inches having already been developed with a very small amount of labor.

The mines were discovered in '69, by a party of adventurous prospectors from Pahranagat, who, with such changes in their ranks as are incidental to and inseparable from a ten years' residence in a new mining camp have, with an abiding faith in the richness and permanency of their mines, remained in the district, sheltered in their rude cabins beneath the frowning bluffs, developing their property to the extent of their limited means, and manfully battling every adverse fortune.

The district has had its little tragedies, as what rich mining camp in this turbulent argentiferous region has not? Away up, near one of the highest peaks, a cedar whispers above the lonely grave of old man McMurry, a talented, kindly gentleman, well known to the pioneers of the State, who was shot down while defending his property from interlopers.

> He said no more, and never will.
> We buried him up in the brush,
> Where the shadows fall from the giant hill
> On his grave with a kindly hush.

And the fate of John Russell, the owner of the celebrated "Inca," while returning from Eureka, after having disposed of a quantity of first-class ore, his fearful death and the mysterious and very suspicious circumstances in connection with it, are still fresh in the minds of the people of this section.

Throughout the length and breadth of our immense mineral area, veins of the richest and freest chlorides known to mining men have been forced to the surface from nature's treasure-house in the bowels of the mountain, as if inviting capital and enterprise and labor to trail them to their fountain-head. At the southern end of the mountain, Messrs. McBurney & Lamb (the former a merchant of this place, and the latter an ex-foreman of the Eureka Consolidated) have a series of mines, and are at present engaged in pushing a tunnel, called the "Great Western," into the mountain, with the most flattering prospects. Immediately north are the Savage, Balbec, Blue Bell and others, the property of Messrs. Service, Putcher, Smith & Co. These gentlemen are pioneers of the district, have remained in it through evil and good report, and have a magnificent property for capital *intelligently handled*. Still further north is the Inca and Auxiliary mines, the property of Mr. George Russell. The Inca is too well and widely known to need but a passing glance. It has been developed to a depth of 300 feet. The ore body in sight varies in width from 5 to 15 feet, and the entire mass will mill from $150 to $200 per ton. Portions of this will go high into the thousands, and it is a fact well known, not only to us, but to the mill men of Kiko, Tyho, Reveille and Hamilton, that the ores of the Inca are so densely impregnated with silver that non-mineral-producing rock, lime, shale and spar, which mingles with it, will yield remunerative returns.

Negotiations are now pending at the East for the sale of this property, and it is to be devoutly hoped, for the reputation of our mines abroad, that they may be successful, and if so, it is again to be devoutly hoped that in order to make the enterprise ultimately successful, the company may place the management in *competent hands*.

Still north of the Inca is the property of the Chicago Company, who performed a small amount of work during '78, and I believe anticipate resuming operations at an early date, and of the Wyandotte Company, an association of Boston, New York and Philadelphia gentlemen. The mines of this company are the Wyandotte, Thompson, Rattler, and others, the Wyandotte being the only one developed to any

Mechanical Progress.

Important California Inventions.

Several valuable inventions have recently been produced by the mechanical ingenuity connected with the Central Pacific Railroad shops, at Sacramento, and which are briefly described in the *Record-Union*. The first which we notice, and which is now in successful operation at the shop, is

A Car-link Machine.

Invented by foreman Stephen Uren, of the blacksmith department, and by the use of which refuse scrap iron is in the brief space of a few moments converted into coupling-links and ready for use. The machine is made by the introduction of an attachment to the ordinary steam hammer, consisting of dies placed in the hammer and bed, to cut the iron to its proper length, curve, bend, lap and weld the links. This is all done with such rapidity that the iron does not lose its heat from the time it is first taken from the furnace until it is complete in links. The process by which this is accomplished may be briefly stated as follows: The refuse pieces of wrought-iron are weighed out and put up in the usual way for blooms, placed in the furnace, and when brought to the proper heat, they are then taken, one at a time, and placed under a 5,000-pound steam hammer, and by a few strokes are formed into billets of four inches square. They are then passed immediately into another furnace, and from thence through the rolling mill, which forms it into bars of the size desired for links. These bars, which are left by the rolling mill at red heat, are at once placed in the link machine, when by a single stroke a piece is cut off of proper length for a link, and the ends scarfed. The piece is then placed under another die of the machine, and a stroke upon each end curves them in shape to properly form, when brought together, one end of the link, while a third stroke with an oval die upon the center of the piece forms it into perfect link-shape, with the scarfed ends neatly lapped together ready for welding. It is then brought to welding heat, when it is again put into the machine, and with a single stroke the link is perfected and ready for use. The capacity of the machine, is 1,000 links per day, requiring 66,000 pounds of iron. The work done by the use of this machine is accomplished in about one-fifth the time required for the same number of men by the old process, and with corresponding economy in fuel. These advantages, together with its simplicity of construction, and the facility with which it can be introduced and attached to steam hammer machinery generally in use, will no doubt secure for it ready and general adoption. Mr. Uren has also recently introduced a process for making

The Best Cast-Steel

From the refuse steel scraps which have accumulated to the extent of hundreds of tons at the railroads shops, and which has heretofore been considered as entirely worthless. Under the process brought forward by Mr. Uren this waste material is readily converted into merchantable bars of the finest quality of cast-steel, and at the reasonably low cost of only about five cents per pound, as against the general market price of 18 cents. The practical working of this method has already been thoroughly tested by the manufacture of considerable stock, and is found in every way to be successful.

Still another improvement, which promises to be of great value to railroad interest, is

A New Wrought-Iron Car-Wheel,

Invented by General Master Mechanic, A. J. Stevens, of the Central Pacific road. The cost of this wheel will not exceed that of the ordinary cast-iron make, while it will be more durable, less liable to accident, and far less in weight. In making the wheel, the rim and hub are forged by machinery into two circular sections, with recesses in the sections of both rim and hub to receive the spokes. The spokes, which are made in the form of an ellipse, with rib in center of each side for increase of strength, are placed in position in these recesses, and the two parts of both rim and hub brought together, thus forming the wheel, but consisting of eighteen pieces, there being fourteen spokes in a wheel. The whole is then taken in that position and placed to a furnace, by the use of a large pair of tongs made for the purpose and operated with the furnace-crane, and when brought to the required heat for welding is placed under a five thousand pound steam hammer, in which are dies of the desired form, and with three strokes it becomes a perfect wheel and ready to receive the steel tire, which is fitted and shrunk on in the same method that the tires of locomotive wheels have been heretofore. One set of furnace men will manufacture from eight to ten of these wheels in a day. The difference in weight between cast-iron and this new wheel is two hundred and fifty pounds each in favor of the latter, which difference in an ordinary train of forty cars will amount to forty tons, or four full car loads of shipping weight. This indicates the importance of the improvement, and if it proves as successful as it now promises, will effect a general change in the rolling stock now in use.

Steels for Hardening and Tempering Purposes.

Hardening and tempering processes are performed upon steel for three purposes:

1. To enable it to resist abrasion and wear.
2. To increase its elasticity.
3. To enable it to cut hard substances and increase the durability of the cutting edge.

Of these, the first is the simplest, because the precise degree of hardness imparted is not of vital importance.

The second is more difficult, because the quality of the steel employed for such purposes is variable, and hence the tempering process must be varied to suit the steel. The third is of the greatest importance, because the articles to be tempered are the most expensive to make, the duty obtained is of the greatest consequence to manufacturing pursuits, and the fine grade of steel employed renders it more liable to crack in the hardening process.

In those mechanical parts of machinery which are hardened to resist abrasion and wear, the quality or grade of the steel is very often selected with a view to obtain strength in the parts and ease of mechanical manipulation in cutting them to the required shape, rather than to the capacity of the steel to harden. Hence, tougher and more fibrous grades of soft steel termed "machine" steel, are employed, meaning that the steel is especially suitable for the working parts of machines. This class of steel is of a lower grade than that known as "tool" steel. It is softer, works, both on the anvil and in the lathe, more easily, and will bear heating to a higher temperature without deteriorating. It approaches more nearly to wrought-iron, and is sometimes made of so low a grade as to be scarcely distinguishable therefrom.

The kinds of steel used where elasticity is desired, are known as spring steel, blister steel, and shear or double-shear steel, although, for small springs, steel of the tool-steel class is often employed.

The steel employed to make cutting tools is known as tool steel, being a fine, close-grained cast steel, harder but less fibrous and tougher than other steels. Treating these steels in the order of their importance, the last named takes precedence. The English brands of tool steel known as Jessops', Hohson's, Sanderson's, Groaves', Stubbs', Firth's, and some others, were for many years held in the most esteem; but of late several American brands are considered equal, and, indeed, by many, preferable, especially the Crescent Steel company's brand of tool steel. The secrets of successful tempering, however, are applicable to all brands of steel, since they consist in the method of manipulation. Whatever brand of steel the toolmaker may use, it is essential that it be as uniform as possible in its grade, so that the tempering process for one batch may be suitable for the next. If this is the case, the temperer is enabled to obtain reliable and uniform results by a constant process, instead of being obliged to alter the process to suit variations in the quality of the steel. Under these circumstances, the experience gained by constant practice is made available in securing the most desirable tempering process for that steel. If the steel varies much (all steels vary to some slight degree), the tempering may, of course, be varied to suit it; but, in this case, the practical man has no means of knowing what variation to make in the process until he has, by a trial, discovered wherein the degree of temper requires alteration or modification.

The preference of an expert temperer for a particular brand of steel is, by no means, to be taken as a proof of the superiority of that steel for the specific purpose. It may be that, under his conditions of manipulation, it is the best, but it may also be that, under a slight variation of treatment, other brands would be equal or even superior. It may be accepted as a rule that the reputation of a steel for a particular purpose is a sufficient guarantee of its adaptability to that purpose, and all that is necessary to a practical man is to be guided by the reputation of the brand of steel, and only change when he finds defects in the results, or ascertains that others are using a different steel with superior results.

Where large quantities of steel are used, the manufacturers in many cases request customers to state for what particular purposes the steel is required, their experience teaching them what special grade of their make of steel is most suitable.—*The Blacksmith and Wheelright.*

Straightening Castings.—Sometimes a casting is warped in cooling and requires straightening before being used. If the piece is to be planed or otherwise finished it should be straightened by heating and placing weights upon it. If it yields to this treatment, it will retain its corrected form after the scale is removed, and through all the after processes. But, if the piece is to be used without finishing, it may be straightened by "pening" with the hammer—striking with the "peno" or wedge-shaped end of the machinist's hammer. This process makes a series of indentations on the convex side of the iron, stretching the "skin" of the casting; but when these indentations are removed by after working, the casting is liable to return to its curved form. In "pening," that portion of the casting that receives the blow should be immediately over the face of the anvil or bench block; in other words, each blow should find a solid resistance, and the casting should be moved along the face of the anvil as the work progresses.

Scientific Progress.

Recent Researches in the Polarization of Light.

Faraday, in 1845, made the important discovery that bodies which (like glass or water) have ordinarily no particular action on polarized light, rotate the plane of polarization when influenced by strong electric or magnetic forces. Many experimenters have since worked in this field, and it has been proved that not only in solids and liquids, but in gases also, an electromagnetic rotation of the plane of polarization may be effected. MM. Kundt and Rontgen have recently described to the Munich Academy experiments by which they prove such rotation, even in the less easily condensed gases, hydrogen, oxygen, atmospheric air, carbonic acid, and marsh gas, and measure its amount. Their method consisted essentially in compressing the gas strongly in a copper tube with glass ends, through which a beam of polarized lime light was passed, the tube being surrounded by a coil of wire for passage of the current. For certain reasons the polarizer and analyzer were placed within or between the glass ends of the tube, and consisted of tourmaline plates. The polarizer end of the tube was fixed, while the rest of the tube, with the analyzer, could be rotated about its axis. The amount of rotation of the plane of polarization was found to differ considerably in the different gases, and to be greater the greater the index of refraction. In one and the same gas with varied density the amount of the rotation is proportional to the density.

An interesting question connected with such researches is that as to the possible influence of the earth's magnetism on polarization of light of the atmosphere. Some time ago M. Henri Becquerel made a striking experiment, in which, a beam of light having been polarized by successive reflections through a tube containing sulphide of carbon, it was found that if the tube was in the plane of the magnetic meridian, the plane of polarization had not the same position when one looked northwards as when one looked southwards. But if the tube was at right angles to the magnetic meridian, the plane had the same position whether one looked east or west, and its position was midway between those in the two other cases. This seemed to indicate a magnetic rotation of the plane under the earth's influence. Recently M. Becquerel has made numerous observations on atmospheric polarization in regard to the earth's magnetism. The plane of this polarization should coincide with the plane of the sun (a plane, *i. e.*, passing through the sun, the point looked at, and the observer's eye), when the sun's plane is vertical, if there were no disturbing influence. Now, looking at a point near the horizon, north or south, or better, near the magnetic meridian, when the sun's plane is vertical, the plane of polarization is found by M. Becquerel to be deflected by a small angle, and the coincidence of the two planes never occurs till after the passage of the sun. It is exactly as if the plane of polarization underwent a rotation, always in the same direction (which with reference to the axis of rotation of the earth is direct), and this rotation M. Becquerel attributes to the earth's magnetism. In the region at right angles to the magnetic needle, the rotation was found to be *nil.*

Noxious Vapors and Smoke.

Some highly successful experiments have been made for depriving smoke of its deleterious compounds. Sulphurous acid and carbon or soot, it is proved, can be completely scrubbed out by a mechanical process. The smoke, in its way to the chimney, is intercepted by two or more wooden racks; between these are dash wheels, which, as they revolve rapidly, throw water from a tank beneath in a fine spray over the racks; the smoke from the furnace is drawn through the chamber by the action of a fan driven at high speed. In the model showing the experiment, the liquid consisted of a solution of soda, which so completely absorbed the sulphurous fumes from burning brimstone that it was possible to inhale the air from the exit flue. Equally effective was the apparatus when turpentine, about the most fuliginous of combustibles, was burned. After its smoke had been washed in the model apparatus, a sheet of white paper was not soiled by exposure to the vapor—no longer smoke—of the flue corresponding to the chimney.

At this stage of the inquiry one cannot say if the experiment shows that erection on large premises will pay, or will altogether act in certain cases, but the experiment with the model, and the subsequent demonstrations of practical use in the chimney of a furnace consuming 50 tons of coal per week, proved the test a complete success. In the latter case a striking proof that the apparatus clears the products of combustion from soot consisted in first placing a piece of wetted linen in the ordinary furnace chimney, when it presented an inky aspect in about half a minute; a similar piece held in the flue from the washing apparatus was scarcely soiled.

Microscopic Discovery of Malarial Poison.

For some years, physicians and scientists have been much occupied in efforts to ascertain the nature of the poison which produces malarial fever, and success has finally crowned these labors, as will be seen by the following, which we copy from a contemporary:

The poison is not cognizable by the senses, nor can it be detected by chemical tests. The air of malarial districts has been analyzed, the soil has been submitted to microscopical examination, but no light was thrown on the subject. But not finding a thing looked for is only negative proof, and by no means decisive in any investigation. One thing was certain, namely, that the poison was generated in salt and freshwater marshes, in wet meadows, from vegetation decaying under a hot sun, in lands alternately flooded and drained, in the moving of earth rich in vegetable matter, and in the drying up under certain atmospheric conditions of stagnant pools. But what the poison was that produced those remittent and intermittent diseases which are known by the various names of marsh fever, malarial fever, fever and ague, and popularly as "chills" and "shakes," has at length been discovered by two scientists, Signor Tomasi, of Rome, and Prof. Kleb, of Prague. After spending three weeks in that fever-stricken region, the Roman Campagna, experimenting on its soils, its atmosphere, and its stagnant waters, they have succeeded in seeing the microscopic fungus, which, on being placed under the skins of healthy dogs, caused distinct and regular paroxysms of intermittent fever, and produced in the spleens of these animals that peculiar enlarged condition which is a recognized part of the pathology of this disease.

The report of their investigations and experiments, and the success that crowned them, was read a short time since in the Academy at Rome, and if further tests substantiate the truth of their discovery, the next series of experiments will have for their object the means whereby these poisonous fungi may either be destroyed or rendered innocuous. The practical agricultural remedy of draining and liming will probably remain the best remedy.

The discovery of the source of malaria in a minute fungus, discernible only under the microscope, merits the applause with which it has been received, and will strengthen very materially the belief in the germ theory of disease which has found in Tyndall one of its ablest advocates.

Wonders of the Telephone.—Capt. John E. Greer, U. S. A., shows how the flight of projectiles can be measured by the telephone, as follows: Hitherto the accurate determination of the time of flight of small-arm projectiles has been practically impossible at long ranges, owing to our inability to see them strike, even when firing over water. The discovery of the telephone has opened up to us a simple as well as novel means of obtaining the time desired, and has also afforded us the means of verifying the formulas by which these times were formerly deduced. In these experiments two telephones provided with Blake transmitters (a form of Edison's carbon telephone) were used. One was placed within a few feet of the gun and left open to receive and transmit the sound of the discharge. The other was in the shelter-proof, which was about thirty feet in front of the right edge of the target. A stop watch, beating fourths of a second, was used in connection with it. The telephone being at the ear, the instant the sound of the discharge was received at the target the watch was started, and, on the bullet striking, was stopped. A mean of a large number of observations, which rarely differed more than a quarter to half of a second from each other, gave the time of flight. The velocity of sound may be readily obtained with the telephone in the same manner.

Fusibility of Metals.—By means of extremely delicate processes, M. Violle has lately determined the fusing points of the more refractory metals. The following are given as the exact temperatures for five of these metals in the order of their fusibility: Silver, 1,749° Fah.; gold, 1,863°; copper, 1,890°; platinum, 3,195°; iridium, 3,510°. It will be seen that pure copper requires a higher temperature to fuse it than gold; ordinary commercial copper, however, melts below 1,035°. Iridium is the most difficult of all metals.

Nitrolin.—A new explosive compound, known as nitrolin, is compounded as follows: From 5 to 20 parts of sugar or syrup are mixed with from 25 to 30 parts of nitric acid in a wooden or gutta-percha vessel. Of this compound 25 to 30 parts are mixed with 13 to 35 parts of nitrate of potassa, and from 13 to 15 parts of cellulose.—*Chem. Centralblatt.*

It is recommended that the manufacturers of ammonia soda calcine it very thoroughly so that it may not contract further on ignition. Furstenau says that the great and unequal shrinkage which this soda sometimes undergoes at a red heat is the cause of the uncertain and unsatisfactory results when it is used in the manufacture of ultramarine.

When gun-cotton is decomposed in closed vessels it gives rise to products which are few in number and simple in character, namely, carbonic acid, carbonic oxide, hydrogen and nitrogen.

Mining Share Market.

The transactions during the past week have held a firmer tone than for some time past. The amount of sales is evidently on the increase, and though, with a few marked exceptions, there has been material advance, there is certainly greater confidence as to the future. The general outlook from the mines is full of promise for a prosperous season. It is from this cause that outside stocks are attracting attention, even from cautious buyers. The developments in many of the class of mines, which the outside stocks represent, are so favorable that they must ultimately come to the front and assume a popular position. It would be invidious, among so many mines of this character, to name any of them; by doing so, and omitting other equally entitled to notice, an injustice would be done to the latter. But it is certain that from all sections of this coast well authenticated statements are continuously received of rich developments being made and rich discoveries consummated. The shipments of bullion are evidences of increasing yield of the mines. Under this favorable state of mining, it is not likely that any severe depreciation in sound stocks can occur. On the contrary, there will be, in good stocks, a gradual and healthy advance in price. There will be fluctuations, but the recede will be temporary, while the advance will be, in the main, continuous.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Eureka Con., Jan. 13, two days past, $63,620 lbs.; Jan. 14, 34,680 lbs.; Jan. 18, total, past week, 227,020 lbs; Wells, Fargo & Co., at Eureka, Jan. 16, $1,000; Jan. 18, $4,377.24; Jan. 18, total, past week, $18,212.06; at Silver Reef, Jan. 10, for one week, $29,773; Tyho Con., Jan. 1 to Jan. 8, $6,000; Stormont, Jan. 10, $7,539.50; Bodie, Jan. 12, $13,329; Standard, Jan. 12, $41,680.48; Noonday, Jau. 12, $8,000; Hannington & Mellor, Jan 16, $4,500; Belmont M. Co., Jan. 12, $2,570.96; Jan. 16, $1,960.35; Bartell M. Co., Jan. 8, $1,784.12; Tyho, Jan. 16, since last report, $3,190; Richmond Con., Jan. 18, during past week, $25,836.61; McMillen S. M. Co., Jan. 11, $2,260; Jan. 13, $4,783; Jan. 16, $1,913.71; Eaton & Bailey, Jan. 13, $1,183.95; B. Weisl & Co., Jan. 13, $1,742.83; Argenta, Jan. 19, $14,400; Leopard, Jan. 19, $3,818.

TYLER'S HAY UNLOADER.—Jerry Tyler, of Milford, Lassen county, exhibited his hay and grain unloader, stacker, barn filler and distributer, Saturday, Jan. 10th, in front of the Stewart House, Susanville. Quite a crowd assembled to examine its workings and discuss its utility, and all pronounce it a success. The hay or grain is taken up in a net, and easily carried to the top of the stack or barn, where it is neatly emptied and distributed. One man and one horse and a hoy can accomplish in a moment what would require an hour's hard work for three men in pitching hay into a barn or upon a high stack. Mr. Tyler will start next week for Reno, and will give exhibitions of its working along the route, thence to San Francisco, where he will have castings made, when he will return and canvass the county for the sale of farm rights. Every man who puts up 50 tons of hay each year can save money by buying one, for they will last for years. Its simplicity is its greatest recommendation.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

DOWNS.—Amador *Ledger*, Jan. 17: Drifting has been on a small vein of very rich ore. At 250 ft a crosscut was run and a large body of rich quartz was found. It has been cut into six ft without getting through it. It is the richest strike in the county off the mother lode.

MELLO MINE.—Work has commenced and the ore assays $30 per ton. The quantity of ore is large.

EL DORADO.

ESPERANZA.—*Democrat*, Jan. 17: The crosscut is in the vein 41 ft, without reaching the hanging wall; all good milling ore. That mine is bonded to a San Francisco company for $30,000.

INYO.

ANTELOPE.—*Independent*, Jan. 17: A two-ft ledge of ore has been struck in one of the principal mines of Antelope district, nearly opposite Bishop creek.

MARIN.

NEW MINE.—An assay of ore from a mine near San Rafael, by C. F. Kirchner, yielded $15 per ton of silver, $3 of gold and 10% of copper. The specimen assayed was picked up by himself as a fair sample of a large amount of croppings. Copper ore containing 10% is valuable without gold or silver.

MONO.

GLENN-DALE CON.—Bodie *News*, Jan. 16: It is on Silver hill; it contains 2,684 ft. ft has three shafts—two inclines, one vertical. The main incline, 506 ft from the south end is down 125 ft, cutting a fissure six ft wide, assaying well. The other incline is sunk 75 ft, following the ledge, which is five ft with 16 inches of very rich ore. The vertical shaft is 60 ft with good ore.

SOUTH BULWER.—In the winze on the 350 level the ledge is four ft.

BOOKER CON.—The plunger pump on the 480 level is now in place, and this insures perfect freedom from water at the 480 level. Work in the crosscut, 400 level, is rapidly advancing; in 95 ft, with prospects of soon cutting the ledge.

ORO.—The west crosscut is in 102 ft. The material passed through is tough porphyry, with seams of good quartz, carrying iron sulphurets and gold. The east crosscut is in 109 ft, passing through a succession of clay and quartz seams.

SOUTH NOONDAY.—The double-compartment shaft is down 126 ft. The ground in the bottom is a red, iron-stained porphyry, one of the best indications of rich mineral in the district. On the croppings of the sand bank ledge an incline shaft was sunk 60 ft, and good milling ore was struck.

ORIGINAL SUMMIT.—The shaft is down 100 ft, following the ledge. It is rich in free gold, and with high-grade ore to the bottom.

QUEEN BEE.—The east crosscut on the 400 level is in 96 ft, passing through a strata of quartz, carrying good ore.

SONORA CON.—The west drift on the 100 level is in 66 ft. The rock is of a favorable character. Stringers of quartz and clay coming in.

STANDARD CON.—The north drift, 385 level, is in 620 ft. The ledge is 3½ ft wide, of good milling ore. An upraise is started from this drift, 500 ft north of the main crosscut. The ledge in this raise is 4½ ft wide of good ore. The north drift is in 200 ft, showing a ledge 2½ ft wide of fine ore. An upraise has been started from this drift 254 ft south of the main crosscut. The ledge here is 3 ft wide and looks well. An upraise has been made from the intersection of the main east crosscut and north drift, 30 ft. The ledge here is 4 ft wide, of very rich ore. The north drift, 500 level, is in 15 ft, showing a ledge 4 ft wide of good ore. The east crosscut, 500 level, is in 145 ft, and is now in very favorable formation. The south drift from the west crosscut, 300 level incline, is in 124 ft. The ledge here is 3 ft wide of good ore. A connection was made between the drift on the east ledge, 300 level incline, to ventilate the workings on that ledge. This ledge was cut in the east crosscut, 400 ft north of the incline, from which a drift was run north 200 ft, showing a ledge 2½ ft wide of good milling ore. The company will now extract ore from this drift. The west side shaft is down 48 ft below the 700 level. In the north drift, 385 level, the ledge is 20 ft wide of good milling ore. In the south drift, 500 level, the ledge is about 8 ft wide, and looking well. The West Standard is 6 ft wide of rich ore.

BULWER CON.—Drifts have been started north and south on the Stonewall ledge, which was cut last week in the west crosscut from the bottom of the winze on the Ralston ledge, 480 level. The north drift is in 12 ft, showing a ledge two ft wide, of good ore. The south drift is in 14 ft. The ledge here is 18 inches wide, and looks well. The west crosscut from the south drift, 380 level, is in 220 ft. The west crosscut from the 400 level of the Bodie mine is in 84 ft. The north drift on the Ralston ledge, is in 10 ft. The ledge is three ft wide, of good ore. The south drift is in 13 ft, showing a ledge two and a half ft, of good milling ore.

SUMMIT.—The north drift, 630 level, is in 37 ft. The ledge is three and a half ft wide. The north drift is in 39 ft. The ledge is two ft wide.

TIOGA.—Active work has been going on the past week. The shaft has reached a depth of 735 ft. Samples of ore taken from the bottom show free gold in quantities. The Syndicate drift is being pushed ahead, and is now 644 ft from the shaft; east crosscut from the Ralston winze, on the 620 level, is now in favorable vein matter; the upraise from the 520 to the 320 levels, on the vein No. 3, is up 57 ft, and in fair milling ore.

MARYLAND CON.—During the past week the main shaft has been sunk 24 ft, the whole bottom in vein matter, carrying seams of rich quartz and clay. The stopes on the 253 level are yielding good milling ore. The ore continues good in the drift on this level. It is expected that the 500 level will be reached by the last of the month, at which point a station will be opened and crosscuts for the company's three ledges started. Rapid progress is being made, and praiseworthy energy is displayed in advancing the work. The machinery works smoothly. Everything around the mine is in good order, and indicates a practical man at the head.

MCCLINTON.—On the 500 level the west crosscut has reached a distance of 245 ft. The character of the ground is porphyry, with stringers and bunches of quartz, and is evidently near the Jayhawk ledge. On the 675 level the north drift has reached a distance of 675 ft, and the ledge is looking well. The water is handled very easily. Everything in and about the mine is working well.

NEVADA.

PLANET GRAVEL.—*Transcript*, Jan. 15: A test washing of 15 carloads of gravel produced a little over $10 of very fine gold. No quicksilver was used, and consequently more or less of the gold escaped. The gravel coming out improves each day.

PROSPECT.—A tunnel run 300 ft. Ledge 16 inches wide with good ore.

PROVIDENCE.—The 1,500 ft of tunnel leading from the 600 level of the old incline has been connected with the new shaft near the center of the claim. The ore bodies are ready for stoping clear to the 1000 level, and have never been broken into only to obtain samples for testing their value.

MERRIFIELD.—*Herald*, Jan. 17: The last clean-up was the most remunerative they have had since the mine first started. The outlook is most prosperous.

MILTON.—Grass Valley *Union*, Jan. 21: The ditches of the Milton company, above the snow line, are choked with ice and snow, as also the ditches of other companies, and an unobstructed flow of water is not expected for some time yet, or until a warm rain shall help to melt the snow.

MARYLAND.—Surveys are now being made on the Maryland mine with a view to the proper location of a shaft and the erection of hoisting works. The Maryland has long been regarded as a property that would make a valuable mine when the necessary development was made. Hoisting and pumping works of strong capacity will be put up to work the mine at least 1,000 ft, while the tunnel will be utilized to drain off the surface water. There is probably no quartz mining property in the State more inviting as a field for exploitation than the Maryland, as its geological features go to show that a strong contact vein runs into, and probably through the whole length of the location, which is 2,000 ft, and is part of the wonderful lode, which on that portion embraced by the Eureka and Idaho mines has yielded over $10,000,000.

MINING ITEMS.—*Herald*, Jan. 20: The sulphuret works of the Murchie mine, commenced operations last Saturday. The mill of the Providence mine has been idle since last Saturday, on account of a break in the Rough and Ready ditch. It started up again yesterday afternoon. A new pump was put into the Merrifield mine last Saturday. The old pumps would not handle the amount of water requisite from the two lower levels.

NEW DISCOVERY.—*Transcript*, Jan. 21: Sharp & Co., who have for some time past been prospecting below the V Flume, near Canada hill, at last have the satisfaction of "striking it rich." The main tunnel was run into the hill a long distance without showing anything more than stringers. A couple of drifts were made with like result. Finally the tunnel was pushed ahead, and after being extended 40 or 50 ft, developed a three-foot ledge that shows very rich in galena and sulphurets. The owners naturally feel much encouraged, and outsiders who claim to be posted say they have every indication of a first-class mine. It is said that if the present prospects hold out, a mill will be erected in the spring.

SAN BERNARDINO.

IVANPAH CON.—A letter from the Superintendent of the Ivanpah Con. mine, dated January 12th, contained the following: "I have much pleasure in reporting that we have to-day struck ore of a very good grade in the shaft of the lower tunnel. We still continue to have ore in the west drift from the Cook shaft." Another letter from the Superintendent, dated January 15th, says: "Since last writing you the shaft in the lower tunnel is showing an increased body of ore and richer in character. The lower west drift from the Cook shaft is still in ore." The last shipment of ore to San Francisco assayed $1,614.86 per ton.

SIERRA.

GRAVEL MINE.—*Mountain Messenger*, Jan. 17: The gravel mining company called the "One Thousand and One," located above Sierra City on Chips hill, are cutting down their tunnel four ft, and retimbering is in progress. The tunnel is in 500 ft. We saw some coarse gold from this claim.

BLUE GRAVEL.—They have sunk a shaft 42 ft into blue gravel, and are now running a tunnel to tap the same. Expect to find pay on bedrock. Tunnel is in 140 ft and channel about 70 ft ahead.

NORTH STAR.—The company, of Cornishmen, have a tunnel in about 300 ft. Prospects good for pay, as they are undoubtedly nearing a rich channel.

LAST CHANCE.—They are running a bedrock tunnel for the extension of the 1001 channel.

LOST CHANNEL.—This mine is running a tunnel under Thompson's ranch, which is in 250 ft.

SAVAGE.—The tunnel is in 500 ft and gravel 300 ft ahead.

MILTON CREEK.—Chinamen have taken out, within the past three months, 240 ounces of coarse gold.

NEVADA.

WASHOE DISTRICT.

UNION CON.—Gold Hill *News*, Jan. 21: On the nine ft of milling ore passed through after the porphyry horse was penetrated, a drift has been started north and is opening up a fine formation of rich ore. On the 2300 level stopes are being opened south from those on the 2200 level of the Sierra Nevada incline. The ore in this part of the mine extends nearly to the Union shaft, and is of fine quality. The work of enlarging and retimbering the drift south from the Sierra Nevada incline on this level has been completed and a crosscut started east which shows signs of approaching the ore body encountered east on the 2400 level. The south drift on this level was last evening within 11 ft of the line of the joint Mexican winze from the 2000 level. When it reaches a point under this winze, connection will be made by a raise of 10 or 12 ft.

UNION SHAFT.—The work of placing the large pumping engine in position is being urged forward as rapidly as the precise nature of such operations will admit. The large cylinders of the engine are both in place, and to-day the dumps for the skips are being removed and the three-decker cages attached. In the shaft the work of preparing for and placing the pumping apparatus progresses well.

BELCHER.—The east drift on the 3000 level has been pushed up to the casing of the ore vein, and there left for the present for fear that water might be encountered by penetrating that casing, and the mine is now handling all the water it conveniently can. The south drift on this level is being driven ahead with all energy, in order to reach a point under the crosscut on the 2700 level, so as to work east and test the vein under the ore streak encountered above.

YELLOW JACKET.—The shaft has attained a depth of 2,850 ft and reached a mixture of quartz, porphyry and dyke. A station set has been placed at the 2866 level corresponding with the 2760 of the Belcher and the 2700 of the Crown Point and Kentuck, at which point connections with these mines are to be made. The north drift on the 2700 level is reaching out toward the Confidence and Con. Imperial, with which mines connection is also to be made.

CON. VIRGINIA.—Preparations are being made for running a drift south on the 2350 level from the C & C shaft to connect with the joint Best & Belcher winze to be continued on down from the 2150 level. A crosscut east from the foot of this winze and on the 2150 level has been started. On the 1750 and 1550 levels the stopes continue their accustomed yields.

OPHIR.—The joint Mexican crosscut west on the 2300 level continues in soft vein porphyry, which requires timbering; total length, 307 ft. Drifts are being run both north and south on the Hardy vein on the 2200 level. The drift south continues in low-grade ore, but it is known that below the level above there is good ore further on. The north drift is in ore of a good milling quality and looks well.

CALIFORNIA.—The northwest drift on the 1506 level is being reopened and retimbered, and from it a crosscut will be run to explore the ground lying beyond the old stopes.

GOULD & CURRY.—By the latter part of this week or the fore part of next, the joint Best & Belcher east drift on the 1700 level will reach the perpendicular of the G. & C. and B. & B. shaft, and as soon thereafter as preparations can be made a diamond drill will be sent up to tap the water there encountered.

LADY BRYAN.—The latest developments have been made by running a crosscut east from a point in the incline 90 ft below the 750 level. This crosscut this morning had the top for five ft from the face, and the face in very fair rock.

LADY WASHINGTON.—A crosscut west has been started on the 1550 level, 500 ft south of the north line. This crosscut will pass under the point in the vein from which the winze was sunk from the 800 level and found some good ore, and will prospect the vein at the depth of 750 ft.

MEXICAN.—The north drift on the 2300 level continues in a heavy vein formation, in which stringers of quartz giving low assays are found. The joint Union crosscut west, 2000 level, is in vein matter, the face 480 ft from the main north lateral drift.

SIERRA NEVADA.—The drift east on the 2300 level, and running from the station of the incline, has passed through 20 ft of ore, giving fair assays, and further work in that direction stopped. The west drift on this level is in an excellent vein formation, carrying stringers of quartz giving low assays. The north drift on the 2200 level from the east shaft continues in fine-looking vein matter, its face 365 ft from the starting point.

KENTUCK.—The drift north from Crown Point on the 2700 level has reached the south line of the mine, and the work of extending it to the Yellow Jacket line has been commenced, preparatory to crosscutting and exploring the vein on this level.

SUTRO TUNNEL.—The north header of the tunnel is making unprecedented progress through Best & Belcher ground, penetrating dry rock which needs no timbering. The south header is in Bullion ground and is also making excellent progress.

CHOLLAR.—The west drift, 2400 level, is nearing the point from which the Potosi branch is to be started.

BEST & BELCHER.—A crosscut joint with Con. Virginia has been started east on the 2150 level, from which a winze is to be sunk to the 2250 level.

CROWN POINT.—The north drift on the 2700 level has reached the Kentuck line and been taken up by that mine.

UTAH.—The south drift, 1750 level, is in 45 ft and cutting a vein formation of porphyry and clay, carrying stringers of quartz. The east crosscut on this level is in 25 ft in vein matter also. The incline is now 135 ft on the slope below the 1750 level.

OVERMAN.—The east crosscut, 1906 level, is penetrating a very fine vein formation of quartz and porphyry, yielding fair assays. This formation was encountered about 40 ft from the lateral drift and continues over 90 ft.

CALEDONIA.—The south drift, 1900 level, is making rapid progress through soft vein porphyry carrying seams of quartz; total length, 465 ft.

BELMONT DISTRICT.

ALEXANDER.—Cor. Belmont *Courier*, Jan. 17: The bullion product of the Alexander mine for December was $37,530.07. So far in January we have shipped only $7,918.48, but our mill has been shut down part of the time to enable us to put in improvements and additions which we expect will more than double its capacity before the expiration of this month.

BRISTOL DISTRICT.

HILLSIDE.—Pioche *Record*, Jan. 18: A large body of heavy carbonate ore has been cut on the east and west levels. The furnace is reducing 50 tons of ore per day. The cupel furnaces are refining a large quantity of bullion.

EUREKA DISTRICT.

THE K. K.—Eureka *Sentinel*, Jan. 15: All the levels in the K. K. are now producing ore of a good quality. Last month the sale of ores was about $10,000, and it is expected that this amount will be largely increased the present month.

BLOSSOM.—The mine was jumped by parties acting in the interest of the company owning the Home Ticket, which the Blossom adjoins. The Home Ticket assert that it is a part of their claim. Mr. McLaughlin is the proprietor of the Blossom, and has not yet decided what steps he will take in the matter.

CONNOLLY.—Mr. M. P. Murphy, who has leased the lower workings of the Connolly mine, has already made developments that promise to lead to something permanent. He has struck a chamber containing low-grade ore on the lower level, and also a good-sized cave, the sides of which are covered with ore of a good quality.

TRINITY DISTRICT.

NUMA.—*Silver State*, Jan. 15: This mine has produced large quantities of very rich ore. For 15 years it has been the touchstone that other mines have been discovered by, and is now probably the richest mine known in the district. N. Duperu, of San Francisco, patented the mine some 10 years ago, and last year it was reopened. Assays of the ore run from $100 to $3,600 per ton of 2,000 pounds, and the best is at the bottom.

THE ore-producing belt leads from Trinity to Arabia, where the famous Montezuma, Hurricane and other mines have done so much to swell the wealth of the world. Gen. Buckner has lately taken steps to patent the Montezuma, and the idle furnaces of the Oreana works will undoubtedly warm toward their old Arabian friends soon. Most of the developed mines could be purchased cheaply, and easily opened by capitalists.

WINNEMUCCA DISTRICT.

RYE PATCH MILL.—*Silver State*, Jan. 19: Angus Morrison and J. L. O'Donnel have purchased a three-fourth interest in the Rye Patch mill and all the tailings which have accumulated at the mill since it was built. They are now repairing the mill, and will put it in first-class order for the purpose of working the tailings and any ores that may be sent to the mill to be reduced.

OHIO.—Frank Snapp informs us that work was suspended on the Ohio mine, at Rebel creek, about a month ago, in consequence of the drifting snow which filled the cut almost every night. Last week work was again resumed on the mine, and five men are now employed drifting and taking out ore. The ledge looks well and the owners will shortly ship another carload of ore.

ARIZONA.

STONEWALL LODE.—*Silver Belt*, Jan. 10: At the Brilliant, Bates and Amador work has been pushed to the ore vein, but not deep enough to show much ore. At the Virginia a tunnel in progress has reached 60 ft.

STONEWALL JACKSON.—They are turning out large quantities of very rich ore. On the the porch of the office are three boulders weighing from 300 to 600 pounds each, bristling with native silver; while tons of nearly the same character of ore lie on the dumps awaiting to be milled. In the office were three silver bricks weighing 420 pounds, worth $6,500. The difficulty under which the company labor is a want of sufficient water for milling purposes, but that can and will be obviated.

ANTLER.—On the dump there is quite an amount of rich ore. Large boulders coated and seamed with native silver, from one-sixtecnth to one-eighth of an inch in thickness, are extracted. The ore taken from against talc formation is chlorate of silver, of a high character. Water has prevented the further sinking of the shaft, but they are running a drift to the northward.

CONTINENTAL.—Work is progressing with very favorable prospects.

FLORIDA.—The shaft is now in about 55 ft, and they expect to strike ore at 75 or 80 ft. The ledge is very wide and spreads as it goes down, having indications of turning out rich in both quantity and quality.

MISSISSIPPI.—But little work has been done yet.

CHROMO.—The tunnel is in 448 ft, passing through small and large veins of ore. On the hill, lying loose, are tons of very rich ore, which can be taken out at a very trifling cost. On the northern side of the mountain an incline has been sunk 50 ft, following a vein of high-grade ore, which assays $526.60 per ton.

CENTENNIAL.—Has wide veins of rich ore.

SUNSET.—Tombstone *Star*, Jan. 15: In the old shaft the vein is from 11 to 13 ft of solid mineral; grade of ore, about $200; vein dips south and strikes nearly east. The new shaft is turning out rich ore; the vein is large; two-thirds of its ore is gray carbonates and chlorides, very rich, and will run to $600; it contains much horn silver.

PROMPTER.—Has a body of ore in a 22-ft shaft 14 ft wide that will grade to $100. They are running a tunnel 220 ft to strike the 60-ft shaft.

MOUNTAIN TOP.—The tunnel shows the same volume and grade of ore as the Prompter.

RATTLESNAKE.—The shaft is 75 ft, all in ore, with but little waste; ore grades $100, while samples run $300 to $400. It is bonded for $75,000.

NAUMKEG.—Has a rich vein of ore in the shaft.

SIDNEY.—Has a 40-ft shaft in a vein of rich ore of same grade as the Naumkeg.

PRONUCER.—Has one shaft 35 ft and one 22 ft, in good ore all the way.

MOUNTAIN VIEW.—The surface is covered with ore rich in horn and chloride silver. Assays run from $100 to $3,500; by picking specimens, higher results could be obtained.

HAPPY BOY.—*Miner*, Jan. 16: The ore is very rich and

Influence of Cut-offs on Engines.

The following report of M. Keller, on a memoir presented by M. Hallauer on "Steam Engines," has been translated for us from the *Bulletin de la Societe Industrielle de Mulhouse*, by S. H. Wheeler, of this city:

The work of M. Hallauer, of which I have the honor to present you a summary, is, as its title indicates, a study on the economical influence of the degree of cut-off in various types of steam engines. It tends also to support, on very numerous analyses, the conclusion of the last memoir of the author, that is to say, the equality, in point of working expense, of Woolf engines and single cylinder engines, the advantage being rather on the side of the latter.

It is divided into three parts: The first comprising the researches relative to double cylinder engines; the second, those concerning single cylinder engines; finally, the third, summing up and comparing the results obtained.

We will follow M. Hallauer successively in the study which employs us, and we will take the order adopted by him; that is to say, that after having studied the double cylinder engines, we will examine those with a single cylinder, summarizing for each type, and drawing conclusions then on the whole business.

First Part—Double Cylinder Engines, Called Woolf Engines.

M. Hallauer cites at first all that has been said on the advantage of engines of this system, and after discussion, comes to the conclusion that the only prime consideration truly eerious and incontrovertible, which militates in its favor, is this: That the difference of the stresses from the commencement to the end of the stroke is not so great as in the other types, and that, in consequence of this better distribution, the working of the engine is much more easy. As to the useful effect of a two-cylinder engine, the brake trials executed under the auspices of your committee on mechanics, have shown that the Woolf engines ahsorhed more power for themselves than the eingle cylinder engines, which was otherwise easily foreseen.

Passing then to the examination of the influence of a cut-off in the small cylinder, M. Hallauer commences by examining the results obtained:

1st. In a series of trials executed by bimself in 1877, on a vertical, beam, Woolf engine, situated at Munster, and coming from the workshops of the Societe Alsacienne de Constructions Mecaniques.

2d. In the trials made in 1876, under the auspices of your committee on mechanics, on a horizontal Woolf engine from the same builders, report of the triale having appeared in the *Bulletin* of July–August, 1877.

3d. In those made in February, 1877, by the Association Alsacienne des Proprietaries d'Appariels a'Vapeur, on an engine at Malmerspach, furnished by the same builders, but fitted with a variable cut-off in the small cylinder, actuated by the governor and put on by the Societe des Ateliers de Constructions Mecaniques de Bitschwiller-Thann.

4th. In the trials made at Saint-Remy by M. Queru, and at Rouen hy the Association Normande des Proprietaries d'Appariels a' Vapeur, on two vertical, beam, Woolf engines from the workshops of Messrs. Thomas & Powel, of Rouen.

Having eliminated the trials in which the verification was not sufficiently exact, M. Hallauer determined the consumption of dry saturated steam per bour, per absolute horse power, per indicated horse power, and per effective horse power, per hour, basing hie calculations on the sum of the calories of heat supplied to the cylinder by the steam and water leaving the boiler; in other terms, hy substituting for the entrained water the quantity of steam which the same number of calories of heat would have furnished to the cylinder as this water has taken there, and taking account also of the calories left in the steam jacket by the steam which is condensed there. He passes then to the analysis of each trial, and determines the quantity of steam and suspended water at the end of the admissiou and at the end of the stroke, the variations of the internal heat, and, finally, the cooling effect Rc of the condenser. This cooling effect is verified by two different methods already explained several times hy M. Hallauer in your *Bulletins*.

I ought to pause here a moment to say a few words on the verification of the trials.

M. Hallauer'e very elegant method of investigation has already heen given in his last work; hut I helieve that it is not useless to repeat it here, in order the better to appreciate its importance.

When it is desired to take account of the quantity of steam expended during a given time by a steam engine, the quantity of water fed to the hoiler is measured. This quantity of water, increased or diminished by a weight easily calculated, according as the water level in the boiler is higher or lower after the trial than hefore, gives the quantity of steam used. A method given hy M. G. A. Hirn, and puhlished several times in your *Bulletin*, suffices to determine the proportion of water entrained in the eteam. This constitutes the direct determination, which is verified in the followiug manner:

Knowing the weight of water and steam supplied from the boiler; also the steam pressure in it, it is easy to determine the number of calories supplied to the engine per stroke of piston. This number of calories diminished hy the external radiation, and by the heat ahsorbed in the work, ought to be equal to the number of calories ahsorbed by the water of condeusation, which is obtained in gauging the water leaving the condenser and measnring its final and initial temperature. The method of performing this has been several times described. The difference hetween the number of calories supplied to the engine diminished by that of the calories absorbed in the work and the external radiation, and that of the calories found in the condenser, divided hy the total number of calories, will give the percentage of error that will have been made.

One word, also, *apropos* of the work in absolute horse power, which has not always been easily understood.

The excellent works of M. Hirn have shown the enormous influence of the internal surface upon the manner in which tbe steam behaves inside the cylinder.

When two engines of different types or different dimensions are compared, or otherwise the work furnished by the same engine under conditions of varying work, it is the influence of the internal surface, which must be determined in order to make calculation, for each trial, of the manner in which the steam is utilized.

Now, whatever may be the construction of the condenser, this influence of the internal surface varies hut little, while the vacuum, and consequently the indicated work, may vary within wide limits. The variable vacuum, entering into the calculation if the engines are compared according to their iudicated power, will tend to falsify the results. It is, therefore, compulsory to suppose that the engines which are being compared are provided with ideal condeusers, furnishing a perfect vacuum behind the niston, and to compare the engines with reference to the work furnished with this perfect vacuum. It is this work which constitutes the absolute work of the engine, and it is the consumption for this absolute work which makes it possible to compare among themselves different engines or those operating under conditions of varying work.

It is well understood besides tbat, from a practical and industrial point of vicw, the better the condenser the better will also be the results. This is an affair of the constructor, and has but little influence on the manner in which the steam hehaves in the interior of the cylinder. The absolute work is then the term of comparison, to employ from a tbeoretical point of view, in comparing between themselves engines of different types, or working under different conditions; but the effective work will always be the term of comparison from an industrial point of view.

This stated, I summarize in the following table the results of the verification and analyses of M. Hallauer, and I arrive with him to the following deductions. (See table I.)

The trials made on the Munster engine, for which thè variation of the work is obtained by means of a throttling by the regulating valve, give, as the difference of consumption per hour per absolute horse power, for the extremes of work 3%, which represents the influence of the throttling.

In passing to the coneumption per hour per effective horse power, the economy is much more considerahle and iucreases to 20%, which arises from the increasing influence of the counter-pressure, as tbe work furnished diminishes, and of the co-efficient of friction, which increases under the same circumstances.

M. Hallauer was led to conclude in his previous work that the most simple method of regulating consisted in a cut-off variable hy hand and a governor operating on a valve, the regulation by hand to he employed for considerable variations, the valve serving to maintain the regular epeed despite the small perturhations in the quantity of work required at each instant.

The author of the work explains also, hy simple considerations hased always on the influence of the cylinder walls, different apparent anomalies, which seem to result from the trials. I will not enter into those details which will necessitate giving again thc whole work; all prove that the practical theory indicated hy M. Hiru, and which M. Hallauer applies here, suffices to explain all the phenomena which take place in the interior of the cylinders. After having studied the condensations and the evaporations in the interior of thc small and the large cylinders, M. Hallauer comes to the following important conclusions, which I collect under a little different form from that adopted by him:

1st. Haviug given a boiler working at 5k 5 of pressure (78.22 pounds per square inch), for example, and a Woolf engine capahle of furnishing at this pressure a maximum force of A horse power, there is a possibility of obtaining, industrially, at least 10% of economy in cutting off iu the small cylinder in place of throttling the steam, when on account of circumstances the engine ought to furnish only the half of the work of A horse power. The economy will diminish as the work approaches to A.

2d. The engine workiug in the neighborhood of its maximum power, its power can be varied 10% by the wiredrawing produced by the valve without any noticeable change in tbe economical regime.

The importance of these conclusions is seen at once. In point of fact, there are few Woolf engines working at their maximum power. Besides some huilders of our vicinity when they furnish an engine, rate it at least one-half less power than it really is.

Thus an engine sold for 100-horse power can ordinarily furnish 200 without heing at its maximum; this style of working presents some practical advantages, hut it is nevertheless true that when this engine makes only 100-horse power, regulated by throttling, it consumes 10% more than it would have consumed if this work of 100-horse powcr had been ohtained by admitting at full pressure, and cutting off in the small cylinder.

I am not, however, altogether of the same opinion as M. Hallauer when he prefers a cut-off variable hy hand; I believe that from a practical point of view a cut-off variable hy the governor works better, for it insures against any neglect of the engineer, who can not nearly so well give the cut-off called for at the moment as when it is left to its own free will; besides we have almost always observed that the cut-offs variable by the governor give a steadier speed than tbose regulated by the valve.

Second Part—Influence of the Cut-off in Single Cylinder Engines.

M. Hallauer proceeds for these engines as he has done for those of two cylinders, he first verifies the trials on which he depends, then he analyzes them.

The documents serving in this examination give the following experiences:

1st. Those executed under the auspices of your mechanical committee in April and May, 1878, on a Corliss engine constructed by Messrs. Berger, Andre & Co., of Thann.

2d. Those enterprises in 1873 and 1875 by Messrs. Hallauer, Groseteste and Dwelshauvers-Dery, under the direction of M. G. & A. Hirn, and executed on au experimental engine, unjacketed and working with superheated steam, or with saturated steam. We group the results of the verifications and of the analyses in table II.

Examinations of these results shows:

1st. That for the Corliss engine with steam jacket there is a theoretical economy (per absolute horse power) of 1% 6 in passing from ¼ to 1-11 cut-off, but that industrially this economy disappears and changes its sign, and there is a practical advantage (per effective horse power) of 4½% by working with a cut-off of ⅛ in place of a cut-off of 1-11.

2d. Tbat for the unjacketed engine without super-heat the economy furnished by the cut-off is much more considerable, since on the Hirn engine working with saturated steam there is a theoretical economy of 7.4% at 1-7 instead of ¼ cut-off, and that industrially this economy still remains at 4%.

3d. In taking account of the difference of the super-heat of the trials I. and II. (196° and 231°—384° F. and 447° F.) it ie noticed that this influence of the cut-off in the unjacketed engine remains with super-heated steam what it was with saturated steam.

Trial III. with super-heat proves still more the great economy of the cut-off in these circumstances, when certain limits are passed, eince between one-half admission and one-seventh there is 15% of economy, which would have been still more considerable if during trial I. the work had been done with the same super-heat as during trial III.

4th. In tbe Hirn engine, the trials with saturated steam give at the end of the stroke the same weights of water, .0940 and .0927, in the cylinder, and the cooling effects by the condenser are also the same, 37.53c and 37.02c; therefore, unjacketed, the same weights of water give the same values of Rc. For the Corliss engine, on the contrary, with different weights of water, .0298 and .0398 at the end of the stroke, give the same valnes for the cooling by the condenser, 11.21c and 11.15c, a result which comes from the steam jacket. For the trials II. and III. with euper-heat, the weights of water at the end of the stroke are .0367 and .0373, and the cooling by the condenser 16.61c and 20.34c, a difference which must be attributed to the super-heat, for in the same conditions the saturated steam gives equal cooling effects by the condenser for the weights of water evaporated at the end of the stroke. Which shows that the super-heat works differently from the steam jacket.

Analyzing the variation of internal heat in the various trials which concern us, and the values of the cooling effect by the condenser which result from differences of cut-off, according as we work with or without jacket, with or without super-heat, M. Hallauer is also convinced of the different mode of action of the jacket and super-heat.

The jacket works more actively than super-heat and in the same sense, during the period of expansion, but becomes disadvantageous during the condensation; for then, supplying heat to the water which covers the interior walls of the cylinder, it augments the cooling effect of the condenser, which is not produced by super-heat, and which renders the latter more econnomical in the majority of cases. Examining, then, the theoretical economy, in comparing the consumptions per hour per absolute horse power and the industrial economy, in comparing them per hour per effective horse power, the author comes to the conclusion with M. Zeuner that high grades of expansion are econonomical from a theoretical point of view, and with M. Hirn, that it is inversely from an industrial point of view.

Thus, the conclusions of these two savants which seem to contradict, are found to agree in taking into account the different considerations which have guided each of them; the one, M. Zeuner, having made the general study of steam engines, in arguing from unrealizable considerations, (impermeahility to heat of the cylinder walls), the other, M. Hirn, on the contrary, having studied them from an industrial point of view, in taking account of the permeability of the cylinder walls to heat and of the work ahsorbed hy friction.

Third part. *Comparison of the different types of engines studied.* The conclusion of M. Hallauer's work comprehends the comparison of two cylinder engines and single cylinder engines, in reckoning always from the analyeis of the trials which have served for the two first parts of the work. He reiterates at the heginning, what he understands hy absolute, indicated and effective horse power.

The absolute power is the work whicb the engine would have given with an ideal conden-

This trial has been neglected on account of not verifying itself.

*Not having the original minutes of the curves, the analysis has not been completed.

ser making a perfect vacuum behind the piston. (It is the theoretical work.)

The indicated work is that furnished directly by the steam on the pistons; it takes account of the influence of the back pressure. (It is the power calculated from the diagram drawn by the indicator.)

The effective power is finally the work industrially available; it takes account of the influence of the back pressure and the friction of the various organs of the engine itself.

This premised, there are two trials verified, the one made on a Corliss engine, ¼ cut-off; the other on an engine at Malmerspach, 1-13 cut-off, the figures of which are as nearly alike as possible.

	Corliss Engine.	Woolf Engine.
Water contained at the end of admission	25%	23.7%
Water contained at the end of expansion	18.5 "	17.9 "
Difference of initial and final heat	1.83 calories	1.21 calories
Cooling effect of the cylinder	8.3 "	8. "

The comparison of these two trials lead to some very interesting conclusions.

A phenomenon to be immediately noticed for the Woolf engine serves to destroy that false idea held till now, that in the two cylinder engines the refrigerating influence of the condenser is reduced one-half.

Indeed, in the small cylinder, the half-stroke cut-off gives rise to an evaporation of 10% 6 of the weight of water contained at the end of the admission, and the internal heat increased much more rapidly than in the Corliss engine. Then, the mixture of steam and water passes to the large cylinder with 13.1% of water, and in place of the evaporation continuing in this cylinder, there is, on the contrary, condensation, despite the influence of the jacket, since at the end of the stroke we find 4.8% more water separated than at the end of the stroke of the small piston. This points to a great condensation at the moment of the entrance of the steam into the large cylinder, a condensation which is so powerful that, in spite of the effects of the jacket, all the steam that is condensed in the large cylinder in excess of that which was already in the small, cannot be evaporated.

In the Corliss engine on the contrary, evaporation is continued to the end of the expansion. It is easily seen, therefore, that the influence of the large cylinder, in case of an expansion commenced in the small one, does not tend always to reduce the losses of heat, but that on the contrary, it can sometimes augment them, which contradicts that which was until now admitted.

The consumptions of dry saturated steam per hour per absolute horse power, give the theoretical economy realized by either engine. If we take the consumption of the Corliss at what it would have been with 1-13th cut-off, which is that of the Woolf engine for the trials which we are comparing, we find that the theoretical economy is 4% in favor of the Woolf engine; but the influence of the counter pressure, and still more that of the friction, reduces this economy as soon as we pass into the industrial domain, it then changes sign, and we find that the practical economy becomes 8.7% in favor of the Corliss.

Comparing the horizontal Woolf engine with the Corliss, in taking account of the absence of compression in the former, M. Hallauer still found a theoretical economy of 4% for the Woolf engine. But this economy also disappeared in practice, and then again, the Corliss engine became industrially superior by 9%05 to the horizontal Woolf engine; nevertheless in taking account of the construction of this latter, the difference fell to 2%, and then the horizontal Woolf engine consumed only 8.8 kilos of dry saturated steam per hour per effective horse power, which would be the minimum to which we could attain by a careful construction of the condenser and a greater compression. In concluding, M. Hallauer collects in a table II, the consumptions of steam per hour, per absolute, indicated and effective horse power, adding the consumptions of coal per effective horse power per hour, in supposing that a kilogramme of coal evaporates 8 kilos of water.

This table shows that the various double cylinder types studied, consumed from 9k 1 to 9k 5 of steam per hour per effective horse power; the Corliss engine with ¼ cut-off consuming only 8k 6, whilst the Hirn engine with superheated steam has only 8 kilos of consumption with 1-7 cut-off. Recapitulating the work of M. Hallauer, which is one of those laborious and conscientious studies, to which he has for a long time habituated our society, is very remarkable in its conclusions and tends to prove once more the impossibility of stating anything about steam engines with the precision of fact, if one does not support himself on verified trials of existing engines.

We have been obliged in this epitome, to neglect many interesting things and to seek principally to set forth the various conclusions of M. Hallauer; but everybody engaged with steam engines will certainly find in his work exceedingly useful material, which can serve in many circumstances. We ought then, with the utmost good will, to thank M. Hallauer for all these studies which make enormous demands upon time, patience and reflection; all which he has certainly not spared in his last memoir. You know besides, that he is clad in truth, as you have been able to judge by the numerous works which he has already presented to our society; of which this last, gives, in some degree, the most interesting practical conclusions.

Useful Information.

Mending Belts.

It is not always economy to replace a partially worn belt by a new one. So long as there are portions of a worn belt that retain a part of their original soundness, it is useful as a portion of another belt. In no case put a piece of new, unused belting into an old or partially worn one; more than eighteen hundred years ago this fact was recognized and recorded, although the word "bottle" was used instead of belt. The uniform tension of a belt is impaired by uniting new and unused leather with that which has grown supple by use. No belt should have more than one butt joint. The pieces should be put together in scarf joints by means of rivets or lace leather; old belts have usually absorbed so much lubricating oil that belt cement—fish glue—will not "take." In riveting, the heads should be on the wearing or pulling side and the burrs or washers on the other. In sewing a lap the awl should be passed through in a slanting direction and the stitches should present the smallest amount of surface on the pulling side. In making a butt joint the lacing should not be crossed on the pulley side. The ends of the belts should always be cut by a try square to insure perfect straightness. In taking up belts, even narrow belts, it is much better to cut and sew the belt *in situ* than to run it off the pulleys. The proper degree of tension can always be thus secured and the belt not be kept too loose nor shortened too much; besides, there is always an uneven strain, liable to work injury to the belt in running it on. The Billings & Spencer Co., of Hartford, Conn., make a handy clamp for this purpose. It is geared and is rapid in operation, and is made in all widths. Perhaps there are other good ones in the market; a good belt clamp should have a place in every shop and factory. If you cut your own lace leather, the handiest way to make laces is, after straightening one edge of the skin, to guide the knife with the thumb instead of a straight edge, under which the leather will stretch and pull. By holding the thumb rigid any width of lace may be assured and the work is very rapidly performed.—*Ex.*

Grindstones.—What can disable a machine shop more effectually than to destroy the grindstone? Unless the loss were supplied by the modern substitute, the emery grinder, to destroy the grindstone would be to wreck the shop. A thorough study of the subject will develop more requirements than many think, and much ingenuity or skill in designing might be displayed in working out the problem. It should be strong, simple and clean; the trough expanded to catch as much as possible of the drip water and grit; a movable shield securely hinged to keep the water from splashing, and yet permit the stone to be used from either side; rests provided upon which to rest tools and the rod for turning the stone, these rests being arranged to move toward the center as the stone wears smaller. The bearings should be generous in size, proper provisions being made for oiling without washing the grit into the bearings with the oil, and the ends of the bearings being protected by some device which effectually prevents the entrance of the grit. The stone should be secured to the shaft by nuts and washers, and the washers fixed so that they cannot turn with the nuts as they are screwed up or unscrewed. In hanging the stone, great care should be taken to hang it true sidewise, not only for convenience in using, but because a stone that is not true sidewise can never be kept true edgewise.

Chlorate of Potash from the Dead Sea.—Chemical analysis having long ago shown that the waters of the Dead sea in Palestine are rich in chlorate of potash, a company has been formed, and already commenced operations, to extract this salt from its waters. It is stated that in this way chlorate of potash can be obtained 30% cheaper than by the cheapest process thus far known; and as there is an increasing demand for this salt, it is a safe and profitable investment. In order to save fuel, which is scarce in those regions, the works are kept in the most active operation during the dry season, when the water is low and the River Jordan does not dilute them much, the water level varying considerably, and consequently the concentration. This body of water, of course, contains the soluble ingredients from the hights surrounding the whole water-shed, of which the rains have made a lye, and solar evaporation has concentrated in that sea.

Cellular Construction.—A good illustration of the principle and strength of cellular construction may be given as follows: Take a piece of tin, some 12 inches long and 6 inches broad. Lay its ends on two blocks. Thus suspended a few ounces of weight bends it down to the ground. But roll it up in a tight roll and you may suspend very many pounds from it without its yielding a particle. This illustrates the strength of cellular construction. On this plan the *Great Eastern* steamship was built, she having, up to the water-mark, an inner and outer metal shell of three-quarter-inch plate, placed three feet ten inches apart, and between them, at intervals of six feet, run horizontal webs of iron plates, which convert the whole into a series of continuous cells or iron boxes.

Incombustible Wood.

M. M. P. Folbarri claims that he has discovered a method by which wood of any kind can be rendered incombustible. It becomes, as it were, petrified, without any alteration in appearance. When intense heat is applied to wood so prepared it chars the surface slowly and without flame, but does not penetrate to any extent, and leaves the fiber intact, whereby, in case of fire, the firemen would have no occasion to fear that the materials on which they tread would give way beneath them, if this operation had been undergone by the wood composing the staircases, floors, etc. The following chemical compound is said to produce the result: Sulphate of zinc, 55 lbs.; potash, 22 lbs.; alum, 44 lbs.; oxide of manganese, 22 lbs.; sulphuric acid of 60 deg., 22 lbs.; water, 54 lbs. All of the solids are to be poured into an iron boiler containing the water at a temperature of 45 degrees C., or 113 F. As soon as the substances are dissolved, the sulphuric acid is to be poured in little by little, until all the substances are completely saturated. For the preparation of the wood it should be placed in a suitable apparatus, and arranged in various sizes (according to the purposes for which it is intended) on iron gratings, care being taken that there is a space of about half an inch between every two pieces of wood. The chemical compound is then pumped into the apparatus, and as soon as the vacant spaces are filled up, it is boiled for three hours. The wood is then taken out and laid on a wooden grating in the open air, to be rendered solid, after which it is fit for uses of all kinds, as shipbuilding, house-building, railway carriages and trucks, fence-posts, wood paving—in short, for any kind of work where there is any liability to destruction.

Wood and Iron Gearing.—When gearing is run at high speed, or in any way subjected to severe shocks, if one of the wheels of a pair has its teeth made of wood and inserted into its rim, it has been found—first, that the elasticity of the wood relieves the shock on the iron tooth and reduces the liability of breakage; second, that in case of breakage the wooden teeth are more liable to be broken, and in consequence the teeth can be readily renewed without sacrificing the entire wheel; third, the impact of iron teeth upon wooden ones makes less noise than that of iron upon iron.

Good Health.

Marvels of Man.

While the gastric juice has a mild, bland, sweetish taste, it possesses the power of dissolving the hardest food that can be swallowed; it has no influence whatever on the soft and delicate fibers of the living stomach, nor upon the living hand, but, at the moment of death it begins to eat them away with the power of the strongest acids.

There is dust on sea, on land; in the valley, and on the mountain-top; there is dust always and everywhere; the atmosphere is full of it; it penetrates the noisome dungeon, and visits the deepest, darkest caves of the earth; no palace-door can shut it out, no drawer so "secret" as to escape its presence; every breath of wind dashes it upon the open eye, and yet that eye is not blinded, because there is a fountain of the blandest fluid in nature incessantly emptying itself under the eyelid, which spreads it over the surface of the ball at every waking and washes every atom of dust away. But this liquid, so mild, and so well adapted to the eye itself, has some acridity, which, under certain circumstances, becomes so decided as to be scalding to the skin, and would rot away the eyelids were it not that along the edges of them there are little oil manufactories, which spread over their surface a coating as impervious to the liquids necessary for keeping the eye-ball washed clean, as the best varnish is impervious to water.

The breath which leaves the lungs has been so perfectly divested of its life-giving properties, that to re-breathe it, unmixed with other air, the moment it escapes from the mouth, would cause immediate death by suffocation, while if it hovered about us, a more or less destructive influence over health and life would be occasioned; but it is made of a nature so much lighter than the common air, that the instant it escapes the lips and nostrils, it ascends to the higher regions above the breathing-point, there to be rectified, renovated and sent back again, replete with purity and life. How rapidly it ascends, is beautifully exhibited any frosty morning.

But foul and deadly as the expired air is, Nature, wisely economical in all her works and ways, turns it to good account in its outward passage through the organs of voice, and makes of it the whisper of love, the soft words of affection, the tender tones of human sympathy, the sweetest strains of ravishing music, the persuasive eloquence of the finished orator.

If a well-made man be extended on the ground, his arms at right angles with the body, a circle, making the navel its center, will just take in the head, the finger-ends and feet.

The distance from "top to toe" is precisely the same as that between the tips of the fingers when the arms are extended.

The length of the body is just six times that of the foot; while the distance from the edge of the hair on the forehead to the end of the chin, is one tenth the length of the whole stature.

Of the sixty-two primary elements known in nature, only eighteen are found in the human body, and of these, seven are metallic. Iron is found in the blood; phosphorus in the brain; limestone in the bile; lime in the bones, dust and ashes in all.—*Journal of Health.*

How Long We Are to Live.

It is not everyone who asks himself this question, because, strangely enough, it is the belief of many persons that their lives will be exceptionally lengthy. However, life assurance companies are aware of the credulous weakness of those whose lives they assure, and have therefore compiled numerous tables of expectancy of life for their own guidance, which are carefully referred to before a policy is granted. The following is one of these well-authenticated tables, in use among London assurance companies, showing the expectancy of life at various ages. In the first column we have the present ages of persons of average health; and in the second column we are enabled to peep, as it were, behind the scenes of an assurance office, and gather from its table the number of years it will give us to live. This table has been the result of careful calculation, and seldom proves misleading. Of course, sudden and premature deaths, as well as lives unusually extended, occasionally occur; but this is a table of average expectancy of life of an ordinary man or woman:

Age.	More yrs. to live.	Age.	More yrs. to live.
1	30	50	21
10	51	60	14
20	41	70	9
30	34	80	4
40	40		

Our readers will easily gather from the above tabulated statement the number of years to which their lives, according to the law of averages, may reasonably be expected to extend.

Antidotes to Dyspepsia.—Sleep will do a great deal to restore the tone of the stomach where dyspepsia results, as it often does, from overwork. Stout people, who have it from overeating, should work out of doors, accustoming themselves to hearty work by degrees. The prescription given by an old physician to alleviate dyspepsia, is to drink half a cupful of boiled water, just as hot as one can swallow it, half an hour before each meal, and I have known it to give great relief. The hot water stimulates the energies of the stomach and dilutes the acrid juices which it secretes. A wet cloth, cold or hot, as feels best, worn on the stomach will greatly strengthen it. If the food is carefully selected to suit a weak digestion, dyspepsia will cure itself. Strong chicken broth, without a particle of fat, may often be taken when other things irritate. Raw beef, very finely minced, like meal, and set in a covered saucer in a hot oven until it becomes pink, not brown, can be taken by the worst dyspeptics. White of egg beaten to a froth, or a spoonful of whipped cream, often will not offend. Dyspeptics should eat sparingly, a spoonful once in an hour or two, rather than attempt a small meal three times a day. Bits of ice, swallowed whole, and frozen cream often relish. But the cream should be entirely without sugar. A bit of licorice or parched dandelion root, or cherry bark, chewed and kept in the mouth, strengthens the digestion sensibly.—*Toledo Blade.*

Colic.—The "colic" is usually caused, first, by costiveness, a stoppage, and then indigestion, causing fermentation and the production of carbonic gas in the stomach and the large bowels near the stomach, the expansion of which by heat produces this pain. It is almost immediately relieved by a full injection of warm water resulting in an operation from the bowels, of course removing the costiveness. This costiveness usually results either from the overfeeding or too frequent nursing of the babe—once in about three hours is sufficiently often—or from the use of too much fine food by the nursing mother. Therefore to prevent these torturing pains, avoid or remove this costiveness as soon as known, by the injections and, great care in the time of nursing, and in the food and habits of the mother. Should the bowels seem inflamed and tender, it is safe to wet a soft flannel in tepid water and wrap around the bowels, covering with dry flannel, being careful to keep the little one comfortably warm. This tenderness of the bowels may be observed by noticing appearances of pain as the bowels are pressed, or when an operation occurs.

The Hands.—In order to preserve the hands soft and white, they should always be washed in warm water, with fine soap, and carefully dried with a moderately coarse towel, being well rubbed every time to insure a brisk circulation, than which nothing can be more effectual in promoting a transparent and soft surface. If engaged in any accidental pursuit which may hurt the color of the hands, or if they have been exposed to the sun, a little lemon juice will restore their whiteness for the time; and lemon soap is proper to wash them with. Almond paste is of essential service in preserving the delicacy of the hands. The following is a serviceable pomade for rubbing the hands on retiring to rest: Take two ounces of sweet almonds; heat with three drachms of white wax, and three drachms of spermaceti; put up carefully in rose water. Gloves should always be worn on exposure to the atmosphere, and are graceful at all times for a lady in the house, except at meals.

Assessment Notice—Gila S. M. Co.

The Week.

A large proportion of our space this week is devoted to a very full and exhaustive review of the mining interests for 1879. This review will be found useful for reference, as it gives in a succinct manner the results of operations for the year past, and the prospects of the coming one. We have given most of the space to California interests, as a detailed review of the different States and Territories would exceed the limits of a newspaper article.

The season is not sufficiently advanced for a revival of business to be manifested, still, our leading merchants say that their sales are more extensive than they were equally early last year. The weather has been very favorable for some days past for the farmers.

Our law markers at Sacramento have not manifested any utile ability; it is to be hoped they will improve before the close of the legislature assemblage.

A terrible explosion occurred in the Lycett Colliery, near Newcastle, England. It is stated that from 70 to 90 lives were lost. The explosion is attributed to the ignition of gas. The fire was raging at last accounts, and the bodies which had been brought out were burned past recognition.

TAGS ON CABLES.—Amateur asks us: "How can I fix tags on round wire cable so that they will stay? I am running incline engine. I use rope strands tied around the cable for tags; but they stay on only a few hours, and the ends wear off and cover the rope from one end to the other." You should raise a strand of the cable, and pass a piece of bright sheet metal beneath it; then line it by winding soft iron wire around it, to keep it in place.

THE President has nominated James Russell Lowell, of Massachusetts, to be Minister to England; John W. Foster, of Indiana, Minister to Russia; Lucius Fairchild, of Wisconsin, Minister to Spain; and Eli H. Murray, of Kentucky, Governor of Utah.

DURING the late freeze in Oregon about one million salmon eggs were frozen at the hatchery on the Clackamas. Every effort was made to save them, but without avail. As it is, about one million and a half of young fish have been safely put into the water.

GRANT and Bayard have been nominated in South Carolina for President and Vice-President.

Mines and Mining in 1879.

Bullion Production—Losses and Gains.

Mining industries and interests throughout our gold and silver-producing States and Territories may be said to have been fairly prosperous the past year, notwithstanding the aggregate amount of bullion turned out shows a considerable falling off as compared with that of the preceding year. Adopting the figures of John J. Valentine, General Superintendent of Wells, Fargo & Co's. express, the product of these years was as follows: 1878, $81,154,622; 1879, $75,349,501; making a balance of $5,805,121 in favor of the former. This difference was due mainly to diminished production in the State of Nevada, where it reached a total of $13,184,235, the decrease on the Comstock lode alone having amounted to $12,454,481. The following is Mr. Valentine's statement of the gold, silver and lead turned out last year in the States and Territories west of the Missouri river; the bullion received at San Francisco from British Columbia and the west coast of Mexico included:

California	$18,190,973
Nevada	21,999,714
Oregon	1,037,961
Washington	85,336
Idaho	2,091,300
Montana	3,623,020
Utah	5,468,879
Colorado	14,413,515
New Mexico	622,800
Arizona	1,942,403
Dakota	3,208,987
Mexico (West Coast)	1,633,571
British Columbia	976,742
Total	$75,349,510

The following table from the same source shows the gross yield, segregated:

Year.	Products as per W. P. & Co.'s statements, including amounts British Columbia and West Coast of Mexico.	Products after deducting amounts from British Columbia and West Coast of Mexico.
1870	$54,000,000	$52,150,000
1871	58,284,000	55,784,000
1872	62,236,959	60,351,824
1873	72,258,693	70,139,860
1874	74,401,045	71,765,610
1875	80,889,057	76,705,533
1876	90,875,173	87,219,859
1877	98,421,754	95,811,582
1878	81,154,622	78,276,167
1879	75,349,501	72,688,888
Gold	43 20-100%	$32,539,920
Silver	50 25-100%	38,623,812
Lead	5 55-100%	4,185,769
Total		$75,349,501

The annual products of lead, silver and gold in the States and Territories west of the Missouri river from 1870 to 1879 were as follows:

	Lead.	Silver.	Gold.
1870	$1,080,000	$17,320,000	$33,750,000
1871	2,100,000	19,286,000	34,398,000
1872	2,250,000	19,924,429	38,177,395
1873	3,450,000	27,483,302	39,206,558
1874	3,800,000	29,699,122	38,466,488
1875	5,100,000	31,635,239	39,968,194
1876	5,040,000	39,292,924	42,886,935
1877	5,085,250	45,846,109	44,880,223
1878	3,452,000	37,248,137	37,576,030
1879	4,185,769	37,032,857	31,470,262

The product of British Columbia, Washington Territory, Oregon, California and Dakota is nearly all gold. The countries, in addition to Nevada, that show some falling off, are California, $729,488; Utah, $595,734 and Arizona $345,580. The largest gain made was by Colorado, equal to $8,000,000, chiefly from the recent discoveries at Leadville. The decrease in California is attributable to a considerable curtailment of the silver production in Inyo county, and a lessened yield of the hydraulic mines by reason of an unusual scarcity of water. That Arizona should last year have gone backward instead of forward in the matter of bullion production is something inexplicable, seeing that the railroad has lately been extended almost to her principal mining centers, and also that her ore-reducing facilities have been much increased, and large amounts of capital invested in her mines during the year. It is the case, however, that some of her more prominent mines, such as the Silver King and the Stonewall Jackson, which, with their showing of rich ores, created at one time no little sensation, have not turned out bullion as was expected, having been barely able to keep up the production made by them 12 months ago.

Dividends.

Of course the question of mining dividends is one of great importance in connection with the production, for they represent the profits. Unfortunately, however, no accurate record of dividends is kept. By far the larger number of mines are worked by private companies, and while their bullion product, passing through the express company, shows, in the gross results, the amount of profits is of course a matter for the owners only. We cannot, therefore, tell anything about the dividends except of those companies which publish annual reports, or which are large corporations, the stock of which is sold in the stock boards. The following table, compiled from the *Mining Record*, shows the results accomplished by some Eastern incorporations, most of the dividends having been paid in New York, Boston, Philadelphia and London:

Name.	Location.	Div's.	Amount.
Empire	California	4	$64,000
Green Mountain	California	0	37,500
Pioneer	California	2	8,000
Plumas Eureka	California	1	60,000
Plumas National	California	6	54,000
Sierra Buttes	California	1	40,000
Findley	Georgia	4	8,000
Richmond Consolidated	Nevada	3	337,500
Tombstone	Arizona	1	50,000
Briggs Consolidated	Colorado	1	8,000
Caribou	Colorado	4	40,000
Climax	Colorado	1	20,000
Chrysolite	Colorado	2	400,000
Horn Silver	Utah	1	100,000
Little Pittsburg	Colorado	12	1,250,000
Leadville	Colorado	6	120,000
La Plata	Colorado	3	45,000
Calumet & Hecla	Michigan	4	1,600,000
Central City	Michigan	1	80,000
Osceola	Michigan	1	60,000
Ore Knob	California	2	97,500
Quincy	Michigan	1	40,000
Total			$4,527,30

The *Bulletin*, of this city, compiles the following tables of Pacific Coast dividends from transcripts from books in their office:

Name.	Location.	Div's.	Amount.
Argenta	Nevada	1	$20,000
Belle Isle	Nevada	6	300,000
Bodie Con	California	6	350,000
California	Nevada	5	1,620,000
Con. Virginia	Nevada	5	1,350,000
Con. Amador	California	1	7,500
Excelsior	California	7	147,000
Eureka Con	Nevada	12	$25,000
Father de Smet	Dakota	1	30,000
Great Western Quicksilver	California	1	12,500
Homestake	Dakota	12	360,000
Idaho	California	12	168,950
Independence	Nevada	3	75,000
Indian Queen	Nevada	1	12,000
Martin White	Nevada	3	90,000
North Bloomfield	California	1	90,000
Napa Con. Quicksilver	California	2	20,000
Ophir	Nevada	1	100,800
Ontario	Utah	12	600,000
Standard Con	California	12	600,000
Total			$9,778,750

This table is no doubt correct so far as it goes, but it by no means goes far enough, for the simple reason that this figures are not accessible from all the companies. It will be noticed that only one gravel mine is mentioned, and not a single drift mine, yet dozens of them have paid dividends regularly. Many quartz mines, unknown to stock circles, are also paying dividends monthly. The published tables of dividends, therefore, by no means give an accurate view of the profits of the mines.

Mining in the Northern Section of California.

Grouping the mining counties of California in geographical order, we remark the following among other noteworthy facts transpiring the past year in connection with mining interests and operations in the northern part of the State:

The quartz interests of Lassen county, though still in their infancy, give promise of value in the future. While the veins there are mostly narrow and somewhat "spotty" the ores are easily handled, and, so far as developed, have every appearance of proving permanent. A pocket containing some $8,000 ore, was recently discovered at Hayden Hill. The veins of Gold Run in this county are reported as showing indications of decided merit. Plumas county also makes a pretty fair exhibit of exploratory work done during the year, the people there having apparently awakened to a realization of the fact that many of the old gravel channels, some of which had been deserted in years past, because they did not meet the high hopes of early miners, will still pay if operated with economy and care. Sinking on the big shaft at Jamison has been temporarily suspended at a depth of 200 feet, for the purpose of getting in new machinery, the owners being determined to bottom the blue lead known to exist at that point. Quartz mining also appears to be looking up in this county. The mills of the Plumas National, Green Mountain, Mexican and other companies have been kept steadily at work and give satisfactory results.

In Sierra county every branch of gold mining is successfully and quite largely represented. The Sierra-Buttes quartz mines show as good a record as any in the State, while the Bald Mountain drift claim mines, after an excellent history covering a period of more than 20 years, still continue to pay well. The Niagara and the Bald Mountain drift claims stand in the very front rank of this class, while the hydraulic mines at La Porte and Brandy City yield, as they have done for a number of years, munificently, the latter during the past year having undergone very great improvement. Several other hydraulic and many drift mines have made a good year's work, and the mining interests of this county generally, may be said to be in a healthful and progressive condition.

In Shasta county vein mining, inaugurated some time ago and since kept up with fair progress made every year, has moved along in its usual channels of late. Some hydraulic mining has also been done in the western part of the county, where there is a good deal of pay gravel, with a tolerable chance for obtaining water, the greatest deficiency in the mines there being lack of outlet, which has much impeded operations on what might otherwise have proved successful enterprises. There are no drift mines in Shasta, and the shallow placers that consisted mostly of gulch diggings, and once afforded good wages to an army of miners, are now pretty nearly exhausted, about all that is done in that line at present being a little hand sluicing.

In the cluster of counties that occupy the northwestern angle of the State, composed of

Trinity, Siskiyou and Del Norte,

Hydraulic mining, the only branch extensively carried on, has met with much encouragement the past year through the increased attention paid to the business by outside parties. There exist along the principal rivers in that section of the State many large bars that are well situated for hydraulic operations, and are known to be rich in gold, but which have as yet been but little worked, no measures having been taken to introduce any large amount of water upon them. There is plenty of water in the neighborhood, and it could be easily carried to points where required for use, but the original stock of miners in that country having been able to make fair wages with such small quantities of water as could be easily and cheaply obtained, have not cared to expend their means in securing an increased supply, nor have they taken steps to induce others to do so. Under this condition of things, capitalists, many of them living from the East, have stepped in, and, through their experts and agents, secured a good many of the best water franchises in that region, some of which have already been utilized through the construction of ditches for conducting large volumes of water upon the mines. The building of other ditches and the outfitting of additional mines will speedily follow, and it will not be long until that entire section of country, arousing from the apathy that has so long characterized it, will be transformed into one of the most lively and largely productive mining fields on the coast. In connection with these water rights a considerable area of good gravel land lying convenient has been by these parties secured, sometimes by location, though generally by purchase. This water, however, is the principal thing, as this is comparatively limited in quantity, while the auriferous gravel is abundant. Whoever owns the water will be able always to obtain readily and at little cost all the mining ground required for its full and profitable employment. And it is in this view of the case that these capitalists, in possessing themselves of the water, have virtually gained possession of nearly the entire country, in which no pursuit can at present be carried on to advantage, except hydraulic and quartz mining, the latter being yet in its infancy, with fair chances of expanding some day into a thrifty, if not a very extensive business.

The Conditions for Prosecuting Hydraulic Mining in These Counties

Are exceptionally good. In the first place, the auriferous deposits are rich and extensive, and of a character that enables them to be easily and cheaply worked. Water is tolerably plentiful, and can, at comparatively little expense, be introduced on the mines, and generally under all the pressure desired. There arises here no trouble from barren stuff's imbedded in or overlying the gravel, nor yet very much from hard cement or the presence of unwieldy boulders. The bars to be worked mostly lie high, insuring ample fall, and where this is insufficient the great rivers, into which nearly all the mines have direct dump, afford perfect outlet, all the tailings dropped into them being carried down stream by the force of the current. There is but little farming land along these rivers, and none that can ever be injured by the mining debris; nor can the latter cause any harm through the shoaling of harbors or navigable waters, as it makes its way into none of these. Hence no complaint of damage done by the tailings from these mines can ever arise, either on the part of the public at large or of private individuals.

Among the properties that have changed hands and the extensive enterprises that have been set on foot in these counties the past year, the following embrace the more important: The old McGillivray ranch, situated on Trinity river, 13 miles west of Weaverville, and comprising a large area of rich gravel deposits, equipped and in working order, with ditches, water rights, etc., has passed into the hands of a New York company—consideration, cash down, $115,000. Though a little out of repair, through neglect of former owners, it is considered a good purchase, and one that under the management of the present Superintendent, John Yule, a veteran California miner, will not be likely to disappoint present owners. There is on this ranch one of the finest orchards and vineyards in Trinity county, though these, in a country where fruits and grapes are so abundant, cannot be made a source of much income, the net profits realized from them not exceeding $4,000 or $5,000 per year.

Commencing in the same neighborhood, and reaching far to the east, are the extensive and valuable gold-bearing lands of the Trinity ditch and hydraulic mining company, with large water privileges, ditches completed and projected, and splendidly outfitted, the washing apparatus here being of the most complete and powerful kind. This property, the largest and one of the best ever aggregated in northern California, is owned by San Francisco parties, who, having purchased it at a very heavy cost, have or are about to associate Eastern capitalists with them in its future conduct. In the same neighborhood, a company, having bought out the right to the entire flow of the North Fork, one of the largest tributaries of the Trinity river, are about surveying the route for a canal to bring the water of this stream on a tract of rich mining ground owned by them on the west side of the Trinity, near Junction City. The improvements contemplated by them will involve an expenditure of $45,000, apart from purchase of water franchise and mining ground, bringing the entire outlay up to about $100,000.

Lying near the southerly extremity of Oregon mountain, not far from the above-described properties, is the Dutton Creek ground, covering a large area of high-grade gravel, lately purchased with the accompanying water franchise of Brown's creek by Judge Thomas Sunderland of San Francisco, at the reported price of $73,000. These grounds will at once be put in condition for active operations, the survey of the ditch line being already completed. The property, with all needed improvements, will cost when completed something over $100,000, and is expected to make a gross annual product of five or six hundred thousand dollars, more than half of it net profit. As regards prospect-

ive valne, this property ranks second to none in Trinity county.

On Taylor's flat, a large har situate on tho east side of the Trinity, 28 miles below the McGillivray ranch, an important enterprise bas lately been set on foot. This comprises ths building of a ditch for conveying 3,000 inches of water on the bar, and the supplying of the latter with powerful hydraulic fixtures and otherwiss putting the property in first-rate condition for gravel washing, which it is expected will commence in the course of a couple of months. This too is an Eastern company, having two or three snbstantial California parties associated with them.

The Buckeye company, organized several years ago, own a large extent of deep gravel banks on Buckeye mountain, also in this county. This was originally n San Francisco company, hut the control of ths property has lately passed into Eastern hands. The ground here is good and carries with it a valuable water right, with ditch and bedrock tunnel nearly completed, the whole being well equipped with washing apparatus. Tho outlay on this proporty to date, approximates $300,000, and while the mauagement has heen a little slow regarding improvements, the enterprise will in tbe snd come ont all right and the investment prove a good one. The gravel beds on Buckeye mountain range from 100 to 800 feet in depth, heing ths deepest in the country, and what is of more consequeuce they carry gold in paying quantities throughout. The Buckeye company have heen obliged to build nearly 30 miles of ditching, an unusual length for that section of couutry, and also a somewhat lengthy hedrock tunnel—a structure, too, not often required there, and hy reason of which preliminary expenses have been increased whils active operations have hsen delayed. Being a strong one, the company will probably not complain much of this hrief postponsment of n success considered altogether certain.

In the northeastern part of ths county, Thos. H. Blythe, the well-known San Francisco real estate owner and capitalist, has heen gathering up a great extent of auriferous ground upon which he designs introducing the waters of Coffee creek and the East Fork of the Triuity, n portion of tho large canal projected for this purpose heing already huilt. On this enterprise Mr. Blythe has expended a good deal of mousy and, considered as a whole, it probably contains the elements of a large success, although the schemo is as yet in hut an inchoate state, the owner's characteristic energy and large means may be accepted as evidence that it will he pnshed to an early completion.

In Siskiyou and Del Norte counties three extensive gravel mining properties, including water rights, etc., have lately heen hought hy San Francisco parties, one of these, known as the Bailey, being situated in the former, and the other two, ths Richardson and the Furguson & Frazier, being in the latter county, and in close proximity to the town of Happy Camp. They all lie on the hanks of Klamath river, which affords them ample fall and outlet. The last two are accontered and making a tolerably large and decidedly profitahle production, hut the other hae no improvements of valne upon it. Those properties are all to be outfitted in superior style, and the present limited supply of water largely augmented, wherehy it is expected that their past production will be increased from three to four-fold. The gravel throughout this region of country pays under hydraulic washing at the rate of 60 cents per cubic yard, the avorago in Trinity county heing not much less. This is from three to four times as much as the average yield in Nevada and other of the more central counties. As the natural facilities for operating in these northern counties are at the same time especially good, they evidently present snperior inducements to those desirous of investing in this particular branch of mining. In concluding our remarks upon this new field of enterprise, it is proper to say that while it offers such manifest advantages for the prosecution of hydraulic operations, it is at the same time rather limited in its scope, the hullion-producing capacities of the country being measured hy the quantity of water availahlo for gravel washing, and which, though very considerable, has now heen so completely appropriated that none can be ohtained except hy purchase, and that at figures which would have heen considered extravagant but one year ago. Nevertheless these franchises can still he obtained at prices that parties having the means to utilize them, through the constructiou of ditches and the purchase of mining ground, can well afford to pay.

Central Mining Counties—Butte, Yuba, Nevada, Placer and El Dorado.

Early in the year work was resumed on the old Banner quartz mine near Tahle mountain, Butte eouuty, in which, over 20 years ago, a disastrous oave occurred, causing the death of several men and leading to a suspension of work in the mine. Ever since it has lain idle, although it had previously yielded over $600,000, demonstrating its productive capahilities. During the year the company now operating it has erected a 15-stamp mill, which, for some months past, has heen and is still running on high-grade ore, showing what could he done with some of our idle mines, if properly managed. The McConnell & Duret Co., near Yankee hill, have also started up their new 10-stamp mill; five stamps are heing put upon the Armstrong lode near hy, and the Buena Vista company contemplates an addition to their crushing facilities.

Gravel mining in Butte is said to he in a flourishing condition. Modoc, Vermilion, West Branch, Big Bar and other companies having resumed work under improved conditions. The Sheppard ditch has been completed to Whisky Flat, giving a fresh impetus to the claims in that section, while the Frost & Reese canal company are now pushing things as fast as the severity of the weather will permit. They propose bringing 5,000 inches of water into Strawherry valley and the adjacent gravel lands, and thereby opening up a large section of country which has heretofors been nuproductive for want of water.

Yuba county is most noted for the several heavy hydraulic enterprises prosecuted within her borders, Smartsville and vicinity being the principal center of these operations.

To the Excelsior company at this place belongs the honor of introducing the electric light, supplying a long-felt want in hydraulic mining. As it is said to work satisfactorily in their mines, many other companies contemplate availing themselves of its advantages.

Nevada County.

Nevada county makes, as usual, a good exhihit of progress, particularly in the department of quartz mining, some new mills and hoisting works having been erected, and several consequential developments made during the year. The Idaho, Providence, Murchie and other companies, which have reached depths of from 500 to 1,200 feet, have found their veins at these levels still strong, and as well-defined and fertile as at points nearer the surface. Encouraged by the success attending former efforts, hoth prospecting and ore extraction have been vigorously prosecuted and attended with good results. Among the new mines coming into prominence here the Live Yankee, situate near ths Providence, is conspicuous, an ore body of extreme richness and great promise having lately heen opened up in this ground. Tho property, which is in good working shape, is owned by Eastern parties who intend to work it for what it is worth and not for a market.

The "trihute" plan of working veins is rapidly growing in favor here, and has heen adopted in most cases where practicahle. It has heen found more satisfactory to all parties as doing away with the necessity of employing so many "hosses," and obviating also the disturhances hitherto growing out of the question of wages. Besides effecting these ends, it places a portiou of the risks on the miners' shoulders, and makes him his own master hoth as to the hours and amount of labor which shall constitute a day's work. It is noticeahle that under this system much more is accomplished, as the remuneration of the miner depends directly on the amount of work he does. Several attempts were here made to work the refractory ores of Meadow Lake the past summer, and, though some of them answered in a small way, nothing has as yet been found that succeeds in handling these ores on a working scale.

While the quartz interests here have flourished, the hydraulic mines have had a short hut fairly prosperous season. The past has heen a good year, too, for drift mining, also extensively carried on in this county, the most active and successful sites of this industry heing on the Liberty Hill divide and the ridge known as Chalk mountain, hoth of which are traversed hy some of the most productive "dead river" chanuels in the country. A rich strike is reported to have occurred late in the fall in the True Blue tunnel on the south fork of Deer creek. This development is one of great interest and importance to the neighhorhood, as it demonstrates the continnity and locates the course of the Red Dog and Chalk Bluff lead, famed in days gone hy for its wonderful fertility. Owing to a partial resumption of operations at various points on Chalk mountain, this locality presents of late something of its former life and activity. This mountain abounds with auriferous leads, the repositories of a great wealth, as shown by the quantities of gold gathered at points where these leads have been exposed hy the action of the streams that cross tbem; and it is time that means should he found to trace these channels up, and secure their contents, heside which the big finds of early times, large as they were, would appear only like a drop in the bucket.

Placer County.

In Placer county we find almost every hranch of mining heing prosecuted actively and successfully. Dutch Flat, Gold Run and the Forest Hill divide are the localities of the more extensive hydraulic operatious. Damascus, Bath and the helt of country reaching from the latter to Yankee Jim's heing the points most noted for drift miniug, which business has recently heen started anew at these and several other localities in the county. Among the prominent hydraulio properties in Placer, the Gold Run, Dardanelles, Pond & Constable and the Breece & Wheeler, occupy the first rank, both as regards extent of ground, water supply, and large and profitahle production. Quartz mining has its seat further west, on the belt of auriferous veins that courses through Ophir, Newcastle and Auhurn, in which vicinage this pursuit flourishes to an extent hardly surpassed elsewhere iu the State. The Julian mine, near Newcastle, occupies a prominent position on this helt, and in some very desirable features stands second to no mine in California, their reserves heing large and the oro of excellent grade.

The Bear River and North Fork Tunnel company are at last making a systematic and determined effort to earry out the object of their orgauization, which consists of driving a tunnel through the ridge that separates the ahovenamed streams, for the purpose of conveying the vast quantities of tailings that havo accumulated in Bear river and its upper tributaries and emptying them into the north fork of the American river. The ends to be subserved by this tunnel would he the supplying of means for re-washing these tailings, which are known to be immensely rich in gold, and also for securing continuous outlet to certain hydraulic mines, which without such relief will, in the course of a few years, he estopped from further gravel washing by reason of the tailings obstructing their dump. The scheme is entirely feasible and if carried out could not fail to prove remunerative and useful. It is one that strongly invites the attentiou of capitalists as promising to be both safs aud profitable.

El Dorado County.

In El Dorndo couuty a good deal of attention continues to be paid to quartz mining. The McNulty, Gold Deposit, Placerville, German, and the Rosecrans companies have all made additions of late to their mills and hoisting works. Ths Placerville (formerly the Pacific) company, hnving added 30 stamps to their crushing capacity, havo now one of the heat equipped properties in tbs State. Hydraulic and drift mining are uot here so extensively engaged in as in the counties further north.

Southern Tier of Counties.

Mining in Amador county, confined almost exclusively to quartz, has made fair progress during ths year. While improvements have been going forward in every direction, the most noted is perhaps the restoration of the old Coney mine, near Jackson, now known as ths Zeile. This property had been lying idle for a number of years, but a company of energetic men knowing its merits have taken hold with a good will, and a 40-stamp mill is now nearly completed. The county contains upward of 25 paying quartz mines. Extensive locations for gravel mining were made the past summer on Mill creek above Volcano, and which it is claimed will pay four dollars per day to the man by ordinary sluice washing.

The Gwin mine in Calaveras county has now been developed to a depth of 1,560, feet and the batteries are kept busy on ore from that level. New hoisting works have heen erected at the Champion mine after repairs made in the shaft, and the owners are now in condition to increase the hitherto very liheral production made hy the mine. The hydraulic and drift mines of this section have also yielded fair returns, the Safe Deposit company having lately made some valuahle improvements in the line of exploratory work and the erection of machinery for reducing indurated gravel.

Tuolumne County.

Tuolumne county has heen extremely fortunate of late, and a general revival of mining interests has taken place there during the past few months. Noted in times past for the number and richness of its pocket deposits, this county adds now to its fame in this respect hy the production of a little honanza of $260,000, which amount was taken out at Sonora a few months since with hand mortars. As a result, prospecting has been the order of the day there, and the neighhoring hills have heen covered with gold hunters who have met with varying success, quite a number of smaller pockets having since been found in the same vicinity. Several new mills have heen erected in Tuolumne during the year, some 16 heing at presont in active operation. A new district called the Olsen is just now causing considerahle excitement, tbe attraction beiug a large vein of burnt looking quartz unlike anything previously found. A town site has been laid ont near the spot, and it is reported that a large force of meu are to be immediately employed on the mine. The Tioga silver district, a late discovery in this county, lies so high in the Sierra that all operations there have heen suspeuded and will not likely be resumed before June. The season closed before any considerable developments could be made, but so far as prospected many of the veins showed promising indications. So many other valuable discoverics and rich strikes have heen recently reported in Tuolumne that it may justly be accounted the rising quartz county of Califoruia.

Trans-Sierra.—Alpine, Mono and Inyo Counties,

Lying east of the Sierra Nevada, have had a somewhat uneven experience.

In Alpine county considerahle exploratory work has been done the past year, and with very fair results. The Colorado company, No. 2, has kept its 20-stamp mill and Frue concentrators busy during the last half of the year, turning out hullion enough to meet the hopes of its friends. A new process of leaching the refractory ores of this seetion is claimed to be a success, making it possible to ohtain a high percentage of the precious metals at a comparatively small cost.

While the gold quartz mines of the Bodie district, Mono county, have about kept up their former rate of production, uo startling developments have been made at that point during the year. Under the exploratory work kept up many claims there have shown such improvement that confidence in the resources of the district has heen well sustained, and there is little doubt hut ore developments of importance will soon be announced.

The fact that Bodie has once or twice in years past heen condemned hy popular judgment and relegated to the wilderness, shows that the superficial style of prospecting hitherto in vogue merits only condemnation.

Probably the hest summary relative to Bodie district we could compile is that showing tbo actual production of the mines for the year. This we take from the *Free Press*, as it shows the bullion shipments tbrough Wells, Fargo & Co. for 1879.

	1878	1879
January	$111,567 07	$201,405 25
February	84,473 56	136,714 44
March	78,449 77	189,404 46
April	76,619 33	238,541 94
May	62,020 15	142,348 20
June	85,912 84	302,885 70
July	110,075 79	172,813 21
August	699 944 33	212,012 10
September	317,020 63	286,288 38

1879 (Sitting Bull)	3,485 00
Total	$73,626 87
NOONDAY.	
1879	$36,532 29
MISCELLANEOUS.	
1877 (Red Cloud, Mexican and Kate Rogers)	$12,500 00
1879 (shipments by banks)	39,000 00
Total	$51,500 00
SUMMARY OF SHIPMENTS.	
1877	$797,022 80
1878	2,129,732 58
1879	2,556,847 58
Total	$5,483,602 03

The percentage of gold and silver in the production of 1879 is shown hy the following table:

Mines.	Gold.	Silver.
Standard Con	92	8
Bodie Con	85	15
Bulwer	92	8
Noonday	70	30
Sitting Bull	00	10
Syndicate	93	7

The followiug tables show the production of previous years:

SHIPMENTS IN 1877.	
Standard	$784,522 80
Mexican, Red Cloud and Kate Rogers	12,500 00
Total	$797,022 80
SHIPMENTS IN 1878.	
Standard	$1,025,383 35
Bodie	1,042,236 80
Bechtel	58,634 93
Red Cloud	1,027 50
Scattering	1,550 00
Total	$2,129,732 58
SHIPMENTS IN 1879.	
Standard Con	$1,448,845 47
Bodie Con	764,067 12
Bulwer Con	241,094 38
Noonday	36,532 29
Syndicate	12,316 38
Bechtel Con	11,506 85
Sitting Bull	3,485 00
Shipments by banks	39,000 00
Total	$2,556,847 58

Prior to January, 1876, hut 18 claims were recorded in the district; from that date until January, 1878, 206 were made, and the bullion yield amounted to $797,022. During the year 1878, $2,100,409 were extracted, and 360 claims were recorded. In 1879, 374 additional locations have heen made, making in all 958 recorded locations—very few of which have begun to yield—and the gross hullion yield since 1872, $6,385,886. There are already erected, exclusive of whims (horse power), 24 steam hoisting works on the following mines: Standard, Bodie, Mono, Bechtel, Blackhawk, Tioga, Summit, McClinton, Con. Pacific, Butler, South Bulwer, South Standard, South Bodie, Goodshaw, Addenda, Oro, Noonday, Maryland Con., University, Queen Bee, Jupiter, Champion, Spaulding and Booker. There aro erected and in process of erection seven quartz mills, containing 125 stamps, as follows: Standard, 20 stamps; Syndicate, 20; Bodie, 10; Miner's, 5; Bulwer and Standard, 30; Noonday, 30; Spaulding, 10.

Conceruing the districts of Lake, Tioga, Homer, Laurel, Prescott, North Fork and Castle Peak, in this county, and all in the same mineral helt, we have given from time to time such information as we could gather; and last week gave a summary of operations among the principal mines.

Inyo County.

Owing to the refractory nature or the ores, its remote position and other causes, Inyo county is not in a very thrifty conditiou at present, though a few of its mines are doing fairly. The Modoc is still actively at work and a rich strike in the Indiana has recently been reported. The Mexicans in the Beveridge and Old Coso districts are still prospering in a small way, working with arastras. A new district, called Breyfogle, has heen organized 20 miles north of

[CONTINUED ON PAGE 60.]

Tem Pahute District.

CONTINUED FROM PAGE 50.

extent. This mine has a present depth of about 150 feet, a very small amount of development, if rumors of the amount of money expended be correct. There is every reason to believe that the Wyandotte Company have an immensely valuable property, intelligently handled, and everything would indicate that they are a substantial, enterprising company, willing to invest their money in legitimate mining; yet they have certainly thus far been unfortunate in their local management, have done as many an Eastern company has done before them, and placed the management of their enterprise and the disbursement of their money in the hands of parties entirely innocent of the slightest knowledge of mining affairs. Although we have for years occupied but a modest position among the mining camps of Nevada, we know that we have every resource and every element of bonanza, and we look confidently for a day in the near future, when Tem Pahute will assume the position to which it is entitled as one of the leading silver-producing camps of the State; and its immense mineral wealth, instead of slumbering in its mountain fastnesses, will be poured into the lap of commerce. NAFUINTAH.

OXIDATION OF IRON AND STEEL WHEN IN JUXTAPOSITION.—In a paper read before the Iron and Steel Institute, at its recent Liverpool meeting, Mr. G. Radcliffe incidentally mentioned a case in which steel boiler plates had, when exposed to the same circumstances as adjoining iron plates, distinguished themselves by pitting more than the latter, the steel plate next to the iron being oxidized considerably more than any other. The following analysis by Mr. Edward Riley gives the chemical composition of the steel:

Carbon	0.330
Silicon	0.102
Sulphur	0.065
Phosphorus	0.066
Manganese	0.518
Copper	0.053
Iron	99.320

Mr. Radcliffe's conclusion, although he does not distinctly state it, is that it will not do to place iron and steel side by side.

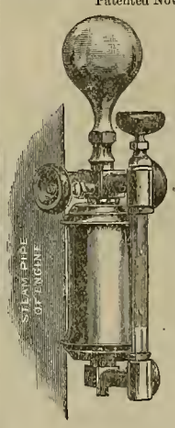
THE FAR-FAMED
AMERICAN LUBRICATOR.
Patented November 14th, 1876.


The American feeds oil into the steam pipe of the Engine, at a point above the throttle valve, THUS INFUSING THE STEAM WITH FOAM OF OIL, and as the Lubricated Steam passes through the Throttle, Governor, Steam Chest and Cylinder, it Lubricates all those parts.
EVERY DROP OF OIL IS VISIBLE as it passes into the steam pipe.
It imparts a regular motion to Engines, because it Lubricates the Governor Valve.
It will pay for itself in fuel every two months, in Oil every seven to 10 months, in wear, packing and labor every four months
It does all the above with absolute constancy, and with the small amount of Oil as shown in Catalogue, which please send for.

DEWEY & CO.,
American & Foreign Patent Agents.
OFFICE, 202 SANSOME ST., N.E. COR. PINE, S. F.
PATENTS obtained promptly; Caveats filed expeditiously; Patent Reissues taken out Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Interferences Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Agency Business promptly and thoroughly conducted.
Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.
The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.
Foreign Patents.
In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Peru, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Roman States, Wurtemburg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.
No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and permanently established.
Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.
We *can and do* get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than any other agents.
The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of inventions discovered here than any other agents.
Situated so remote from the seat of government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.
Confidential.
We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars free.
Home Counsel.
Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.
We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.
Remittances of money, made by individual inventors to the Government, sometimes miscarry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.
Engravings.
We have superior artists in our own office, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

W. BRUCKNER'S
ROASTING FURNACE
AND
Ore Pulverizers.

(Awarded the Premium Gold Medal at Naples, Italy.)

The furnace is especially adapted for roasting rebellious ores; there are more than fifty in use in Colorado, giving perfect satisfaction.
The Ore Pulverizer is built in different sizes. It is preferable to Stamp Mills because it requires less power and less repairs than Stamps. No extra expense for setting up, and no foundation. Less weight and less cost than stamps.
Furnished also in sections for packing.
For circulars and prices apply to

W. BRUCKNER,
Mining Engineer,
328 Montgomery St., room 16

PIONEER REDUCTION WORKS.

G. F. DEETKEN - - - Manager.
Channel Street, off foot of Fourth, San Francisco, Cal.

Highest price paid for Sulphurets, Arseniurets, Tellurides and Gold Ores generally.

METALLURGICAL WORKS,

STRONG & CO., 10 Stevenson Street, S. F.
ORES SAMPLED, TESTED, ASSAYED.

Ingersoll Rock Drills.

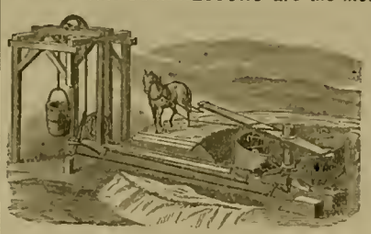
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.
The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

SUB-IRRIGATION.

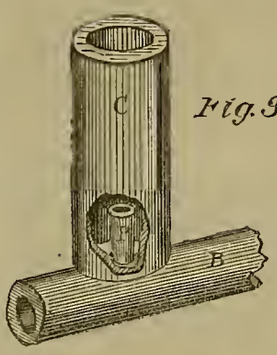


Fig. 3.

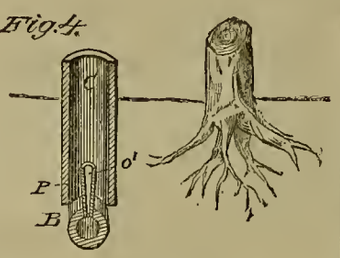

Fig. 4.

—FOR—

Orchards, Vineyards, Small Fruits, Alfalfa, Lawns, Vegetables, Etc.

The Asbestine System consists in conducting the water in concrete pipes laid below reach of the plow.
It saves from three-fourths to nine-tenths the water used in surface irrigation.
It is under perfect control, and can be applied wherever irrigation is needed.
The surface remaining dry there is no need of Summer Cultivation, either before or after irrigating.
The soil is never excessively wet *and cannot bake*, but remains moist, loose and at a nearly uniform temperature, promoting a long-continued Summer's growth.
Anything which the soil lacks as plant food (manure, lime, etc.,) can be easily, directly and economically applied in liquid form; the pest of the vineyard—phylloxera—can thus be easily reached.
No grading is necessary, as the system works perfectly on hillsides and undulatiog land.
Roots *cannot* get into the pipe, neither can it *suck mud*—difficulties never overcome by any other system of sub-irrigation.
The pipe is made continuously with a recently patented machine which *makes and lays* it in the trench, following all the undulations and curves.
Water is not kept in the pipes; but is applied about twice a month.
Three men will easily lay 1,200 feet of two-inch pipe in 10 hours.
This system and machines used are fully protected by U. S. Patents.
Our pipe machine makes the cheapest and best tile drain known, and is especially valuable for making and laying pipe for conducting water from springs, out of canyons, etc.
For further information, circulars, etc., address WILSON & BROWER, General Agents for California, Sacramento, Cal., or

Asbestine Sub-Irrigation Co.,

Los Angeles, Cal.

SHEET IRON PIPE.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Arteeian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

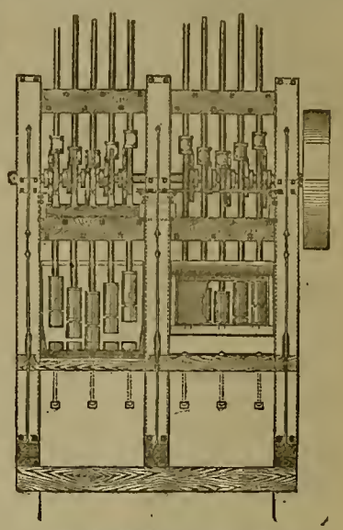
Machinery.

GOLD AND SILVER
Grinding and Amalgamating
MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chlorodizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.



SPERRY'S
Wrought-Iron Frame
FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.
We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

$2,550.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city:
Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Huerne, John Marquis, B. McDougal & Son, Wm. Mooser, Wm. Curlett, Meeker & Banks, W. C. Hoagland, S. & J. Newsom, B. Henrickson.

Mines and Works of Almaden.

Translated from "Annales des Mines"

BY S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (postpaid) 50 Cts. Published and sold by DEWEY & CO., [202 Sansome Street, S. F.

CONTINUED FROM PAGE 53.

free from sulphurets. The lead is three ft wide, and the ore extends from wall to wall. Assays go over $2,000 to the ton.

SILVER KING.—J. S. Mansfield has bonded 60,000 shares of the Silver King mine for $1,200,000. This is the interest held and controlled by J. M. Barney, and as there are only 100,000 shares, it will give Mr. Mansfield the controlling interest in the mine and mill property.

IDAHO.

PARADISE.—Yankee Fork *Herald*, Jan. 10: The new tunnel tapped the vein about 100 ft below the old one, and the workmen are driving ahead in three ft of very soft chloride ore that assays from $50 to $300. It now shows a chimney of at least 100 ft of this quality of ore, and how much farther it extends will be proved as the tunnel advances. There is every indication that the present fine body of ore encountered in the lower tunnel extends throughout the location. The Paradise is now developed to that extent that it adds another to the list of paying mines of the district.

ITEMS.—*World*, Jan. 16: Walt, Coffin & Co. have opened their mine on the extension, where they have a two-ft vein of ore that will go $100 per ton. Mr. D. Bacon has struck rich prospects in his mine, three miles south of Shaws' Mountain. Mr. Plowman speaks in flattering terms of Shaws' Mountain district, which he believes will be a good camp next year. Besides the mines that are now being worked, he says there is abundance of ore in that country that will mill $20 per ton.

Hofmann's Patent Process.

EDITORS PRESS:—In your issue of Decemher 17th, Mr. Deetken expressed bis opinion ahout Hofmann's process, which, I think, was not correct. It was nowhere alleged that these processes in themselves are new; but the comhination of two known processes is new. There was also nothing written ahout "silver-bearing gold sulphurets," hut "auriferous silver ores;" although there is not the slightest douht that this process is applicahle to gold sulphurets with the same advantage. Mr. Deetken says that he introduced the Patera process, preceding Plattner's, at the Eureka mine, Grass Valley, in 1865 (?). He writes, also, "in my hands, hoth methods gave equally as good, or, in other cases, as poor, results ou such argentiferous gold ores as I treated, with the advantage in favor of the Plattner-Patera against Patera-Plattner method, on account of simplicity of the former." So simplicity decided in "experiments," of course. I have often had au opportunity to ohserve that the hest process, in unskilled hands, gave a poor resnlt, and it is very questionahle whether the "experiments" of Mr. Deetken have heen executed with the same precision as Hofmaun's practical work of five months, with an extraordiuary result. Tho success is the *"argumentum ad hominem,"* not the failure. But, after all, Hofmann's process has nothing to do with Patera, hefore or after Plattner. His process is a comhination of Kiss and Plattner's processes. There is a similarity, hut no identity, hetween Patera and Kiss' process; and, among others, the most important difference hetween the two is that the Kiss process extracts gold, where Patera's does not.

There is a particnlar circumstance in Hofmann's process, and probahly also in the comhination of Patera and Plattuer, which, if not strictly observed, results in an imperfect extraction of gold. If, after using the byposulphite of lime for the extraction of silver, the ore has not heen washed perfectly, so that some hyposulphite—eveu the least quantity of it—remained in the mass, a poor result will he the consequence.

Another of your correspondents could not see a novelty in Hofmann's process. The novelty is the comhination, crowned with success. But these gentlemen are patentees themselves, and I shonld like to know where the novelty is in a patent process; for iustance, in the plain Plattner's chlorination process or in the use of suhchloride of copper for amalgamation of silver ores? I wonder also, that after I pnhlished "Kustel & Hofmaun's process," ten years ago, a comhination of Patera & Plattner's processes, *first practiced by Kustel & Hofmann*, how it happens that nothing was made known at that, time ahout those "experiments" in Grass Valley?

Mr. Deetken calls also Hofmanu's attention to several piles of sulphuret tailings, assaying from $12 to $18 per ton. In this case there is only one thing proved, viz., that he who left $18 in the tailings did not uuderstand how to treat the sulphurets properly. G. KUSTEL.

ACADEMY OF SCIENCES.—The regular semi-monthly mocting of the California Academy of Sciences was held on Monday eveniug last, President Davidson in the chair. Among the donatious were specimens of conifers from Santa Lucia mountains, collected by Prof. Davidson, and some petrifactions from Florence, Arizona, presented by Dr. Harkness, showing the marks of stone-cutting instruments. B. B. Redding read an interesting paper ou the "Buried Treasures of Our Ancestors," referring to the finding in several localities of numerous plates of obsidian, the uses of which were an archæological problem. His theory, horn of his obserʼvations among those tribes of Indians in California and Oregon that still use the how and arrow, was that the obsidian was collected for the manufacture of arrow-heads. He had found that mineral was the mainstay of several tribes, who made journeys of sixty miles to collect it on Mount Shasta, and frequently fought battles with other tribes to get at the precious mineral. Prof. Davidson described the general facts connected with the recent eclipse, his remarks being given in another column of this issue.

Mines and Mining in 1879.

CONTINUED FROM PAGE 57.

Panamint, where what are spoken of as promising discoveries have heen made, though not enough work has yet heen done ou the lodes to determine their value.

Mariposa County.

Mariposa has made hut little progress during the year. The Hite mine has added 20 stamps to its crushing power, indicating that there is plenty of ore still in sight in this mine, despite the large quantity already extracted. The Furguson company still keep their mill husy, with satisfactory results. The old Virginia, recently purchased hy Eastern parties, is turning out satisfactorily. The present owners purchased a large amount of machinery, which for years lay idle in Hunter's valley, and erected from it a very good mill, with which they hope soon to reimburse all expenditures and afterwards earn fair profits.

Discoveries of tin are reported in Fresno county, hut at points so remote that, everything considered, they are not probably of much practical value. During the summer a numher of gold and silver-hearing ledges were discovered in the eastern part of the county, some of them of great size and possibly of value. They lie in an elevated region, where the working seasons are so short that their development, if undertaken, must necessarily he slow. The New Idria, in this county, contiuues to rank among the leading quicksilver mines of the coast. Many other mines of this metal are located in the vicinity, hut they have not heen developed, owing to the low prices for this metal prevailing for some time past.

Monterey, San Luis Ohispo and Santa Barbara counties had in the early part of the year quite a breeze of excitement over the reported discoveries of placers within their limits. It has heen found, however, upon trial, that these diggings will pay only the smallest wages, hardly more than a dollar a day to the man on the average.

Rumors of gold and silver discoveries in the Santa Cruz mountains and other points in the Coast range have heen rife during the year, but little has come of them.

The Carmelo coal mine near Monterey, a late find, is producing an article of fuel which compares favorably with Wellington coal, and finds sale in this market at about $10 per ton.

Some placer mining is going on in San Bernardino county, and more might he done were the water supply more plentiful.

The working of the tailings from the old Gold Mountain mill employs a number of hands, and is said to he remunerative.

The Ivanpah section is struggling again to get on its feet. Two mills are running there, and the mines though somewhat spotty and irregular contain many small but very rich pockets that hring the ore up to a pretty high average grade.

From the Julian and Banner quartz districts, San Diego county, hut scant information has come to hand, while the placers discovered last year at the base of the San Isidro mountains failed to show staying qualities, the gold being scarce and water in limited supply.

Quicksilver.

With the exception of quicksilver and coal, not much has heen done the past year towards utilizing our useful metals or minerals; the had condition of the markets and the cost of production here having discouraged efforts in that direction. The quicksilver yield of California amounted for the year to 73,684 flasks, heing over ten thousand flasks more than was made the preceding year, and much the largest annual production ever turned out hy our home mines. Prices meanwhile have shown some improvement, advancing from five to six cents per pound towards the end of the year, when they ruled at ahout 41 cents. The prospect at present is that the market will remain firm and most likely show a further advance, as it now transpires that we have for some time past heen considerahly under-estimating the world's consumption of this article. The year opens with an improved outlook for California mine owners, who for the past three years have made hut little money out of the business, owing to the extremely low prices of quicksilver. The following tahle shows receipts of this metal at San Francisco for the year, with names of principal mines now heing worked in this State:

Receipts of Quicksilver in San Francisco for the Years 1878-79.

CONSIGNEE.	Mine.	Flasks. (1878.)	Flasks. (1879.)
Thos. Bell & Co.	New Almaden	15,249	20,700
M. Dore	Guadalupe	9,072	15,540

November	6,775	6,509
December	6,130	5,794
Total	63,484	73,684

Borax.

Unlike quicksilver, last year's product of horax shows a great falling off as compared with that of the year hefore; the quantity of this salt turned out hy the horate fields of California and Nevada has, in fact, hecn diminishing steadily and rapidly for the past four or five years; the low prices that have prevailed having rendered the husiness not only profitless, hut, to such manufacturers as persisted in carrying it on despite natural disadvantages, wholly ruinous. Even the Riddell, California company, who possess great natural facilities for the cheap prosecution of the husiness, found it expedient to suspend operations for a time last year, not resuming them till the month of August, since which they have turned out at the rate of ahout 100 tons per month, the total production of the coast, nearly all made hy this company, having amounted to 1,554,986 pounds for the year. In 1876 there were gathered from domestic sources 5,180,810 pounds of marketahle horax, the product dropping the next year to 3,727,280, and in 1878 to 2,802,800 pounds, the rapid declension being due mainly to the low prices brought about through a mistaken idea on the part of the foreign consumers that the horate deposits in California and Nevada were so extensive and prolific as to threaten an immediate glut of the market. This having turned out otherwise, the stock has everywhere run low, causing a slight advance in price, at present 8 to 10 cents per pound in this market. With the check given to home production, importations of horacic acid have heen quite heavy at the port of New York the past year, suggesting the propriety of some protection heing extended to the home interest in the shape of a slight duty on this article.

Coal.

Coal mining on this coast has heen tolerahly active the past year, 387,000 tons of this fuel having heen extracted during the year. Of this total, 230,000 tons came from mines on American territory, and the halance from Vancouver Island, British Columbia. From the Mt. Diahlo mines in this State, 134,435 tons were raised, 45,909 from Coos Bay, Oregon, and 135,012 tons from the Seattle mines, Washington Territory. The Bellingham Bay mines, in that Territory, made no production the past year, though it is expected that extraction will soon he resumed at that point. Receipts of Rocky Mountain coal, some of which came to this city a few years since, have this year ceased altogether. The output from the Ione mines, Amador county, amounting to 765 tons in 1878, and 3,458 tons the year hefore, has also heen discontinued. From the mines heing opened at Carmel Bay, Monterey county, 425 tons, first receipts, have come to this market the past fall; also 845 tons from the Tacoma mines. Extraction from the Carhondale pit amounted last year to 1,229 tons, against 4,022 the preceding yoar. With a somewhat diminished home product of late, imports of this article have also decreased, though they still continue large, aggregating over 200,000 tons last year, the principal part coming from Australia, and heing employed here in the rolling mills and for the manufacture of gas.

The Mt. Diahlo coal is used mainly for steam purposes, heing employed to that end hy the foundries, machine shops, mills, factories, etc., and also by our harhor tugs and river steamers, the Vancouver heing preferred hy sea-going craft. Operations at the Mt. Diahlo mines are at present very active and likely so to continue for some time to come. At Coos Bay some revival of mining is also reported, and it is prohahle the quantity of coal raised at that point will he larger the current year than for some time past. To the Newport mines the steamers *Arcata* and *Gussie Telfair* will make regular trips, freighting down coal. At the Eastport and the Oregon mines work will also he pushed. The latter is situated on the Isthmus proper, at the head of deep-water navigation, where extensive improvements have been made and some good coal ohtained, none of which has, however, yet found its way to the San Francisco market.

Five miles from navigahle waters are the Utter and Northern Pacific mines, from the former of which several thousand tons of coal of excellent quality have heen shipped to this port.

On the Northern Pacific property a tunnel 650 feet in length has heen run, which cuts a vein of coal 4½ feet in thickness. This tunnel extended will intersect several other veins, the larger of which are from five to six feet in thickness.

These mines are reached from navigahle water sufficient to float a vessel of a thousand tons, and hy a railroad five miles in length.

The Coos Bay coal is of the soft or brown variety, and of superior quality, heing suitable for steam or domestic uses, and fully equal to the Seattle coal.

Copper.

In copper mining, which during the past three or four years had dwindled to very meager proportions, some signs of a revival are to he detected. The receipts of ore at this point during the past twelve months were insignificant, consisting of some small lots from various California mines, amounting on the whole to only a few hundred tons. Several small lots from Del Norte county were of very high grade, and a contract has heen made for the early delivery here of 600 tons of a like quality. At Spenceville, in this State, extensive works have just heen completed, whereat large quantities of ore will he treated hy the lixiviation process. At the Newton mine the same method has heen adopted and a large amount of copper ore will there also he handled the present year. The Eagle mines of Calaveras county, having been relieved from the legal troubles that emharrassed the company, will at once resume operations, and as the price of copper has somewhat improved of late, a general if not very marked revival of this industry may soon he looked for.

It would seem as if with such an ahundance of the ores of this metal within easy reach we ought to mine and manufacture sufficient for our home wants, if not some to spare. It is a fact, however, that while we are producing and shipping a limited quantity in a crude state, there exists as yet no very large and complete estahlishment for its manufacture into a merchantahle shape. This is due, in part, to the more attractive forms of mining for gold and silver, and in part to ill-advised ventures made in copper mining hefore conditions justified the same. We helieve, however, that a fair amount of capital could now he profitahly employed in the erection of copper reduction and manufacturing works on this coast. Such an estahlishment would immediately stimulate to activity a great numher of copper mines which now lie idle hecause they cannot pay the heavy freights and other expenses accruing on ores shipped to distant markets. Under the present conditions we find it impossihle, except in rare instances, to handle ores containing less than 15% of the metal, whereas the average of all beneficiated in England does not exceed 5%. As we are rapidly gaining on that country in many other branches of industry, it seems strange that we should be hehind hand in this, where our advantages are as three to one.

Our immense heds of good iron ores remain untouched. Our tolerahly ahundant deposits of petroleum are heing partially utilized, hut, as yet, on no large scale, and with hut a partial success. Our sulphur hanks, also quite large, have heen opened and supplied with reduction works, hut have, as yet, turned out only a limited quantity of the refined material, owing to the local requirements heing met in so large degree hy importations from Italy and Japan. While we have antimony, nickel, plumhago, manganese and various other metals and minerals of economic value in great ahundance, none of these have been utilized to a noticeahle extent the past year, the entire ore movement at this point having been less than for some time hefore.

NEVADA.

The most notewortby event connected with mining operations in this State the past year is the marked decline that has occurred in the product of the Comstock mines and the failure to open up any new ore bodies of large value on that lode, notwithstanding the heavy expenditures made in prosecutiug explorations along it meantime. About the middle of the year the Sutro tunnel, having heen brought to completion, hegan soon after to extend some relief to a portion of the mines that had much water to raise, and later on to several others that had heen connected with the lateral tunnels driven toward them. The revenues of the tunnel company in the interim remain small, the quantity of ore extracted from the mines subject to royalty heing inconsiderahle. As regards the prospects for early ore developments of importance on the Comstock range, it is impossihle to speak with assurance, the hest authorities on the subject heing not agreed on that point. Despite these uutoward results, work on the leading mines is kept up and even pushed with energy, as it will no douht continue to be throughout the present year.

At several other localities in the State a good degree of activity has also prevailed, notahly so at Eureka, Tyho and Tuscarora, ahout Columbus, in the Bristol, the Paradise, and one or two other districts, at all of which places the mines are looking and yielding well, while at some valuable ore finds are reported for the year. At several localities in the State mining has languished, while at a few the experience had on the Comstock has, in a small way, found its counterpart. The long and costly tunnel heing driven under Treasure hill, White Pine, hy the English company owning mines there, has failed to develop any valuable ore hody, or even strong signs of such, notwithstanding work has heen kept in progress most of the year. The outlook for that unfortunate locality is by no means cheering. The large shaft being sunk on the Real Del Monte ground, at Aurora, in the Esmeralda district, has gone steadily downward without encountering ore, though late indications are considered favorahle. Should this shaft prove a success, it would lead, no douht, to a revival of operations in that neighhorhood, a great many mine owners there awaiting the results of this experiment to determine whether or not they will again resume work on their claims. Should it, on the other hand, prove a failure, such result would be likely to delay any general resumption of work ahout Aurora, and possibly lead to its indefinite postponement.

As the Comstock may he supposed to have reached its minimum of production and there

are now a good many fairly prosperous mines in Nevada, with others just coming into honanza, and even whole districts that promise an early increase of their present yield, it may be expected that the bullion product of this State the present year will equal if it does not surpass that of 1879. Eureka, Tuscarora, Paradise, Tybo, Bristol, Como, Grantsville and the Candelaria or Columbus being some of the districts which may be expected to sustain and perhaps advance their present production.

Other Statee and Territories.

Touching the value of the precious metals likely to be extracted in the other bullion-producing States and Territories tho current year, it may be observed that some increase on last year's yield may be looked for in the case of almost every one of them, if the reports coming to us through the usual channels of information are to be relied upon. Arizona will this year begin to realize more fully something of the benefits that must surely come to her through the liberal investment of outside capital, the erection of additional reduction works, and the extention of the Southern Pacific railroad almost to the center of the Territory, to say nothing of the aid and encouragement she may be expected to derive from other roads approaching her from the East. The outlook for that country is good, to say the least.

Aside from some addition to the means employed for extracting and handling the ores, a slight appreciation in the prices of lead can hardly fail to stimulate mining somewhat in the Territory of Utah, where this industry is at present in a generally healthful condition. It is agreed on all hands that Colorado will be able to maintain her present rate of production, and may even advance it to the extent claimed by the local press and other recognized authorities of that country. The deposits at Leadville, though shallow and failing to yield anything like the values predicted for them at the time of their discovery, have, nevertheless, made a marvelous production, with a chance of being able to keep it up for some time to come. Dakota and Montana will also be sure to make some gains this year, while New Mexico, Idaho and Oregon should at least hold their own. Washington Territory, through the placers lately discovered on Skagit river, will do much better this year than ever before, while Alaska, though she may not swell the grand total much, will come in for the first time as a bullion producer.

News in Brief.

THE Princess Louise is about to return to Canada.

THE will of Frank Leslie is to be contested by his son.

THE School of Design in this city opened with 43 pupils.

RUSSIA is still secretly continuing her preparations for war.

NEGROES are arriving in Kansas from Texas in great numbers.

THE Duchess of Marlborough relief fund amounts to £19,000.

MAYOR KALLOCH'S condition is causing his friends much anxiety.

GOLD placers have been discovered near Hopland, Sonoma county.

IRA GILCHRIST, a well-known architect in Napa county, is dead.

PROCESS-SERVERS in County Mayo, Ireland, are having a rough time.

A CONCORDAT between Germany and the Vatican is about concluded.

THE damage in Washington Territory by the late storm is placed at $50,000.

GEORGE BRAGG was accidentally hung recently in Douglas county, Oregon.

AN excursion to this coast on a large scale is to take place from Boston in April.

A DARING robbery was recently perpetrated in broad daylight in a Chicago street.

CHANCELLOR HARTSON was elected on Friday last Assemblyman from Napa county.

THE murderer of Jacob Swanger, at Hillsboro, Oregon, has confessed his crime.

IN the recent fight with the Montenegrins the Albanians lost 45 killed and 60 wounded.

SILVER in London, 52⅜; consols, 97 15-16; 5% U. S. bonds, 105⅜; 4s, 107¼; 4½s, 111.

THREE persons were killed and twenty injured Friday, at Southport, Eng., in a railway collision.

DR. CONGAR, of Pasadena, has sold, so far this season, 65,000 grape cuttings, chiefly the White Muscat, for raisins.

IN the State Assembly it has been agreed to refer all hills hearing upon the Chinese question to the Committee on Chinese.

IN San Francisco, half-dollars are quoted at par; trade dollars, 95 buying, 96½ selling; Mexican dollars, 96 buying, 96½ selling.

IN the State Senate the question of reference of bills to the San Francisco delegation, has been decided in favor of the delegation.

THE Republican Legislature of Maine on Saturday elected and inaugurated Daniel F. Davis, Governor, together with the balance of the State officers.

WITHIN the last 13 months 172 bears have been killed on the sheep ranch of Hanson, Porter & Russ, Humboldt county, and between 250 and 300 wild cats.

NOW that Bishop Haven has fallen a victim to malarial fever contracted in a needless visit to Africa, many influential Methodists are bestirring themselves to abolish the practice of sending a bishop abroad every year, and are advocating native resident bishops.

STEEL CASTINGS.—The Chester Steel Castings Co —office, 407 Library St., Philadelphia, works, Chester, Pa.—have in the last few months doubled the capacity of their works by lengthening their main foundry building, and adding to it an L 60x80 feet, and have also erected a larger furnace, larger steam engine and boilers, etc. They are doing double the work they were in the spring. Are filling orders for steel castings from nearly all the locomotive builders in the United States, also from railway companies, engine builders, machine shops and agricultural implement manufacturers, and for wood-working machinery.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

A Cylinder Preseman

Of good experience wants a situation in a S. F. or interior office. Understands running an engine. For a steady situation will accept moderate wages. Address "No. 2," this office.

An Engineer

Wants a situation to run a stationary engine in the city or country. Will accept a moderate salary. Address "No. 1," this office.

SAMPLE COPIES.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

EXTRA COPIES can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Atlanta Mining Company.—Location of principal place of business, San Francisco, California. Location of works, West Tintic Mining District, Juan County, Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the Second day of January, 1880, an assessment (No. 1) of Five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, No. 420 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Fifth (5th) day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Friday, the Twenty-Fourth (24th) day of February, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

A. F. McGREW, Secretary.

Office—Room 7, No 420 Montgomery street, San Francisco, California.

Butte Hydraulic Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 2) two levied on the Thirty-first day of October, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
E Poirson	13	2½	$25 00
L Lapierre	22	2½	25 00
H Marceux	24	2½	25 00
J B Lussier	25	2½	25 00
John Britt	26	2½	25 00
Geo W Deitzler	37	5	50 00
N Desautelle	41	2½	25 00
Jos Lucier	42	2½	25 00
N Goldtree	43	7½	75 00
Geo Moreau	44	5	50 00
Z Gervais	45	10	100 00
Geo Moreau	46	5	50 00
Geo W Deitzler	47	15	150 00
A S Hawes	17	10	100 00
J Callandreau	4	10	100 00
A M Wilder, Trustee	1	10	100 00
A L Leugfeld	5	5	50 00
L L Dennery	6	5	50 00
W E Lutz	7	5	50 00
Geo. H. Powers	11	5	50 00

And in accordance with law and an order of the Board of Directors made on the 31st day of October, 1879, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the company, room 3, No. 220 Sansome street, San Francisco California, on Monday, the 22nd day of December, 1879 at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

L. L. DENNERY, Secretary.

Office, room 3, No. 220 Sansome St., San Francisco, Cal.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock of the Butte Hydraulic Mining Company is postponed to the Fifth day of January, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock is postponed to the second day of February, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

San Francisco, Cal., January 3d, 1879.

Gila Silver Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Reveille Mining District, Nye County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of January, 1880, an assessment (No. 6) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, Safe Deposit building, 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Seventeenth day of February, 1880, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the Ninth (9th) day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. W. PARRISH, Secretary.

Office—Room 7, Safe Deposit Building, No. 328 Montgomery street, San Francisco, California.

Gover Mining and Milling Company.—Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given that at a meeting of the Directors held on the 24th day of December, 1879, an assessment (No. 40) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the second day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the First day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale

W. O. WILSON, Secretary.

Office—402 Front street, room 8, San Francisco, California.

Rocky Point Mining Company.—Location of principal place of business, San Francisco, California Location of works, Placer County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the Fourteenth day of January, 1880, an assessment (No. 2) of Ten Cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. Gold coin, to the Secretary, at the office of the Company, room 1, No. 314 Bush street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 20th day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Thursday, the 11th day of March, 1880, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors.

A. C. TAYLOR, Secretary pro tem.

Office, 314 Bush street, San Francisco, California.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX) is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

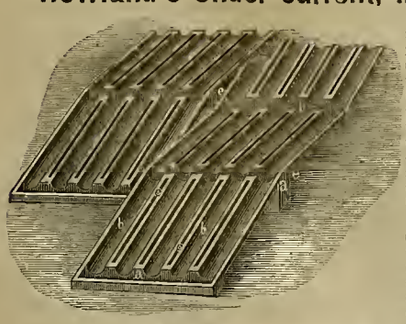
Send for Descriptive Circulars containing testimonials of well-known parties who are at present using them.

Howland's Under-current, Mill and Sluice Riffle.



This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

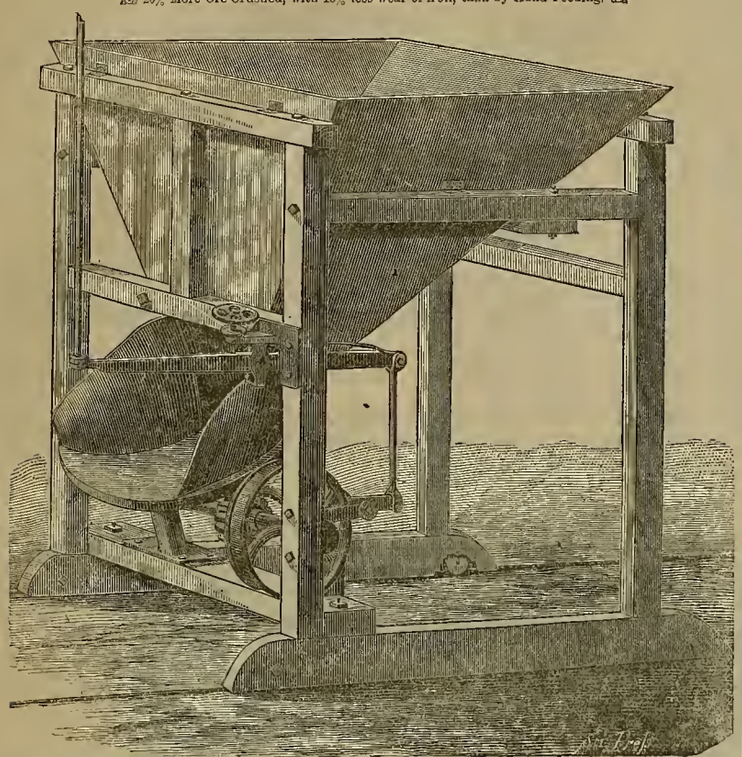
$1,000 CHALLENGE ORE FEEDER,

FOR QUARTZ MILLS.

Awarded First Premium at the 10th and 12th Industrial Fair of the Mechanics' Institute.

☞20% More Ore Crushed, with 15% less wear of iron, than by Hand Feeding.☜



It may be considered as now fully demonstrated, by careful and long-continued 'experimentation, that the plan upon which a perfect Ore Feeder must be constructed is that of the *carrier*, and not that of the shaking table. Uniform and accurate feeding is not possible upon the latter plan. The ore must be evenly carried, upon a steadily advancing plane or table, to the line of discharge, and there simply *dropped*. Spasmodic or jerky contrivances will not answer the purpose for wet, sticky ores.

We warrant the Machines to give perfect satisfaction, and to be better and more durable Feeders than any other in the market, and will sell them as cheap as any other of their class.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, JANUARY 31, 1880.

VOLUME XL Number 5.

Protecting Stockholders in Mining Corporations.

Assemblyman Felton has introduced several hills dnring the present session of tbe Legislature looking towards reform in the matter of the management of mining corporations. Tbe following are the important sections of one of thom:

SECTION 1. It sball not be lawful for the directors of any mining corporation to sell, lease, mortgage or otherwise dispose of the whole or any part of the mining ground owned or held hy snch corporation, nor to purohase, or obtain in any way, any additional mining grounds unless sucb act be ratified by tbe bolders of at least two-thirds of tbe capital stock of sucb corporation. Snch ratification may be made either in writing signed or acknowledged by sucb stockholders or by resolution duly passed at a stockholder's meeting called for that purpose.

SEC. 2. All stock in eacb and every mining corporation in this State shall stand in the books of said company, in all cases, in tbe names of the real owners of sncb stock or in the names of the Trustees of snch real owners, but in every case where snch stock shall stand in the name of a Trnstee, the party for whom be holds sucb stock in trnst shall be delinquent upon said books and also in tbe body of the certificate of such stock.

SEC. 3. It shall not be lawful for any corporation, or the Secretary thereof, to close tbe hooks of said corporation more than two days prior to the day of any election. At such election tbe stock of said corporation sball he used by the *bona fide* owners thereof as shown by the books of said corporation, unless the certificates of stock dnly endorsed he produced at snch election, in which case said certificates shall be deemed tbe highest evidence of ownership thereof.

One of the other hills, introduced hy this gentleman, amends an act passed March 21, 1872. The first section of the bill is the all-important one, and that amends the first section of the act referred to as follows: Upon the petitiou of the *bona fide* owners of one-fourth of the capital stock of any corporation formed for the purpose of mining, to a Superior Judge of the county where said corporation has its principal place of business, to the effect that they are severally tbe *bona fide* owners of the number of shares set opposite their signatures to the petition, said Superior Judge shall issue notice to the shareholders of said company that a meeting of the shareholders will be held, stating the time not less than five nor more than ten days after the first publication of such notice designating tbe said place of meeting within said county, and tbe subject to he taken into consideration, the removal of one or more directors or other officers, which notice shall be signed hy said Judge, and shall be published daily in one or more daily newspapers published in said county at least five days, and not exceeding seven before the time of said meeting. It shall be tbe duty of tbe Secretary of said corporation to produce at sucb meeting the stock and all other books of said corporation, sbowing the owners of stock therein, and any failure of the Secretary to produce such books shall be doemed a contempt of the Court of which said Judge making the order is Judge, and he shall be imprisoned by order of said Judge until be produce such books, and shall also be fined in a sum not exceeding $1,000. A *bona fide* stockholder sball be deemed to be the actual owner of tbe stock, whether issued to him or to another in trust for him. Proof of ownersbip of stock sball be made hy the production of tbe books of the said corporation, or tbe production of certificates of stock. In all cases the certificates of stock shall be considered the bighest evidence of ownership.

Mining and Farming.

It has become almost a chronic condition of the press in agricultural distriots to nnderrate tbe benefits wbiob mining confers upon the community at large. We do not charge upon it any animus in so doing. It thoroughly understands all the facts and principles incident to farming, and though it may sometimes make slight errors in matters of detail, they are no more frequent than are similar errors in mining papers. If it really could comprehend the vast amount of labor which any large mine calls into activity, both directly and indirectly; if it could appreciate the fact, that tbe product of the gold and silver mines increases the metallic base of wbich the standards of value are composed; if it would duly consider that the miners consume no inconsiderable portion of the farm products, it would turn from its inadvertent error and give due credit to this valuable industry.

There is scarcely an industry extant whicb is not called upon to supply the wants of the miners; from the blacksmith at his anvil through all the ramifications of labor; from the one-horse cart with its limited means of transportation to the long train of beavily laden cars; from the rude flat-boat on the river to the well appointed steamer with its freightage capacity notated hy its tens of thousands of tons; from the laboratory to tbe more extensive manufacture of chemicals; from the muscular exertions of the individual to the powerful force of the most ponderous engine; from the limited garden to the farm with its multitude of acres, each and all of tbese cbannels of labor derive a portion of thoir support from the workers in the mines. But this item of benefit arising from mining, great as it really is, sinks into insignificance when compared witb the facilities whicb the mines afford to all of them for interchanging tbeir products through tbe medium of tbe precious metals whicb they yield. Were it not for coin as a standard of value, there could be no extensive oommercial or industrial pursuits maintained in vitality. The farmer could not dispose of the products of his farm and take in exchange the wares of tbe manufacturer, because his wants would not demand such an exchange. The railroad could not he constructed by paying its workmen in tickets for transportation; they would not ride enough in a year to pay for a month's wages. No branch of industry could sustain itself by making its employees receive the products of its work for tbeir labor. It is here wbere tbe advantages of mining are manifested, in that it affords a circulating medium—a standard of value—by wbicb all mercantile and commercial balances can be equitably adjusted and settled; and the interchange of commodities can be extended to the utmost limits.

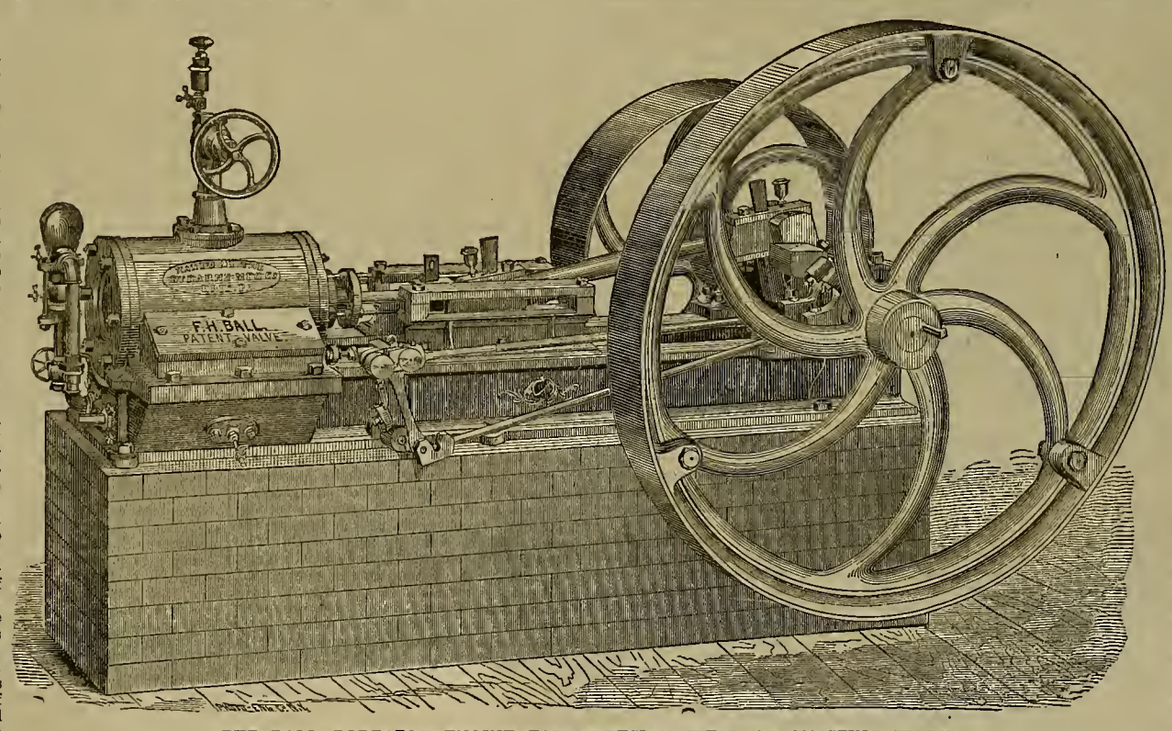
Nor are these other branches benefited by mining products only in the production of the coin-making metals. They actually owe tbeir gigantic proportions to the yield of tho mines. What would agriculture, transportation, manufactures, commerce, art, science, and, in short, every human industry now he, if the mines had never produced the one article of iron? What would bave been tbe condition of tbe buman race if this one metal had never been dug out of tbe earth hy the miner?

We do not wish to be understood as caviling at otbers for holding the mining industry in an unappreciated view. We merely desire to open their eyes to the utility which attends upon its exertions. We wish to convince them that were it not for the standard of value, and the other metals which the mines producc, there could not exist the wondrous civilization, with all its attendant elevating influences and ennobling qualities, that now confere its inestimable blessings upon mankind. We wish to draw their attention to the fact tbat tbeir own welfare is dependent upon tbe success of tbe mines, and that tbe mining interest should receive from all a genial recognition and a fostering care,

Ball's Portable Engine.

We illustrate borewitb one of F. H. Ball's patent portable engines, made hy the Stearns Manufacturing Company, for whicb Tatum & Bowen, 329 Market street, in tbis city, are agents. Tbe engine is especially adapted to drilling artesian or oil wells and for boisting, or any work where it is desirable to run an engine botb backward and forward and to bandle it from a distance.

The valves are held to tbeir seats by steam pressure, and made to follow their own wear, and are so constructed that there is no more pressure upon them tban is necessary to keep them steam tigbt, so tbat the engine can be reversed witb ease without shutting off tbe steam, wbich gives it all the advantages of a balanced valve, without tbe disadvantage of becoming leaky soon, wbicb is, and always has been the trouble with balance valves. The reversing gear is very simple and effective, and arranged for taking up the wear in every part. The balance wheel is made with special reference to the requirements of drilling artesian wells. It is in two parts, so that a light wheel can be used in starting a well, which is a great advantage, and as the work progresses and a heavier wheel becomes necessary, the other part can he attacbed. This facilitates drilling very much. The pillow blocks are furnished witb large oil reservoirs, and the babbit lining or boxes which form the bearings of the shaft are cast in a finished mold, so that tbey are interchangeable, and when worn out can be replaced witb new, which, when done, brings the sbaft into perfect line again. The shaft is very heavy and has long bearings. The engine is very heavy and strong all through, and is built for high speed and hard work, and will stand more neglect and abuse, and do well, than any engine ever offered to the public. Every nart of the engine is duplicated perfectly, from the cylinder or hed-plate to the smallest piece, so that it can he renewed when worn out, without any trouble or any machinist to put it together. During tbe last year over 200 of these engines have been sold in the Pennsylvania oil regions. They have recently been introduced on this coast as being specially adapted for certain kinds of work here.



THE BALL PORTABLE ENGINE FOR ARTESIAN WELL OR HOISTING WORK.

THE Western Union Telegraph Company has received advices from the New York office that, owing to the opening for business of the new French cable, a reduction of 62½ cents per word will he made in all cable messages from California to any portion of Europe outside of Great Britain and Ireland, to take effect on February 1st. No reduction in rates to Great Britain and Ireland will he made until tbe new Cable Company is prepared to compete tbere.

THE Board of Supervisors of San Francisco bave, by a vote of 7 to 5, determined to issue bonds to the extent of $1,500,000, for the purchase of Lake Merced.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Fresno County Mines.

EDITORS PRESS:—In the mining matters of Fresno county, there is no decrease in active work or prosperity, except such temporary cessation of work in the higher mountains as has been made necessary hy a severe wiuter and heavy enows.

The Kentucky Gravel Mining Company Has renewed its work near Millerton, under a new management, after eeveral months stoppage. They keep a force of eight men steadily employed. They are satisfied that they have not yet got hack to the bottom of the old river hed, in which their deep gravel deposits were made, hecause the dip, as they work hack from the prcsent river hank of tho San Joaquin, opposite Old Fort Miller, is still downward as they get farther from the river.

Hampton, Donahoo & Co., the present owners, recommenced their piping ahout Jauuary 1st, and results for tbe first two weeks are entirely eatisfactory.

The White Rock Mine,

In Fine Gold gulch, owned hy Hampton and Gault, of which some account was given in the MINING AND SCIENTIFIC PRESS last summer, has since August last heen developing occasional epots or "pockets" of reddish quartz, partly decomposed and quite rich in a pure free gold. Your correspondent has examined several specimens from euch pockets, and they are very eimilar to the rich rock of A. O. Bell's Life Preserver mine, near Auburn, Placer county, and answer very well the descriptions of the noted red cement claimed to have heen found years ago in Mono couuty.

In mortar prospects some of this finest rock has yielded at the rate of $800 per ton. Three cleanings have lately heen made from au arastra that is run by horse power. The reeults were good, averaging from $40 to $50 per ton. One of the latest and most promising mining enterprises in that district is

The Fine Gold Bedrock Fluming Company.

It is controlled by Hampton and Gault. Two years' work has already been done on it. The object of the undertaking is to drain some two miles of the hroad hed of Fine Gold Gulch creek that it may be thoroughly worked to hedrock. Already in digging the tail-race, which has heen completed ahout a mile and a half out of the two proposed, aud in the middle of the stream as a bedrock flume, fine nuggets of pure gold from 50 cents to $8 in value have heen found in cousiderahle quantities. In this work they go down from two to ten feet, the latter in "pot holes." These places are cleaned out hy diverting the stream for a time; the holes are afterwards allowed to refill. This enterprise embraces six claims and the company expect to complete the two miles of the tail-race this year. The whole hed of the stream will then he worked. A favorable sign is, that as the work proceeds, the results nearly pay expensee. Preparations at other points are heing vigorously made this winter to prese the prospecting aud development of the mining interests of Fresno county the coming summer, in the higher mountain rogions along the upper San Joaquin and King's river. I am reliably informed that the

Very Valuable Enterprise Mine,

Near Fresno Flats, is now heing worked with two arastras iustead of the one with which such excellent results were obtained last year. Its yield aud prospects continue as good as ever. It is claimed by some of the miners of this conuty that extensions of this very rich and peculiar ledge of gold quartz have been traced some 15 miles from the original ledge. It is also claimed that the "Lost Shipe mine" on King's river in this county, has heen re-discovered, and proves to he quite as rich as repreeented hy the traditions that tell of its first diseovery twelve years ago. J. W. A. W.

Borden, Jan. 19th.

UTAH DISTRICTS.—The Utah mining dietricts nnmher over eighty. They are found principally in a line from northeast to southwest throughout the Territory, or clustered near Salt Lake City. The location is accounted for by the fact that prospecting has followed the Mormon trails, if not on them, then parallel and contiguous thereto. I givo the names and locatione of the principal districts, with their distances from Salt Lake City: The Park, Big and Little Cottonwoods, American Fork and Snake Creek are all within a distance, east and southeast, of from 25 to 35 miles. Bingham Canyon is about 25 miles southwest; Camp Floyd, Ophir, Stocktou and Rush Valley are from 45 to 50 miles west and southwest. The Tintic district is in the valley of the same name, 75 miles to the southwest. To the south and eouthwest of Salt Lake City and the Union Pacific road lies Beaver county, from 200 to 250 miles distant. It contains Frisco, Star, Beaver Lake and Lincoln districts. Mt. Nebo district is 80 miles directly south. The Alta district is ahout the same distance. The Silver Reef is over 300 miles distant.—*Silver Reef Miner.*

A Review of the Modern Doctrine of Evolution.*

[By PROF. E. D. COPE.]

The doctrine of evolntion of organic types is sometimes appropriately called the doctrine of derivation, and its supporters, derivatists. This is hecause it teaches the derivation of species, genera and other divisions, from pre-existent ones, by a process of modification in ordinary descent by reproduction. The opposite or creativist doctrine teaches that these forms were created as we see them to-day, or nearly so; and that the natural divisions and species of organic heings have never been capahle of change, the one into the other.

I.—The Evidence for Evolution.

The reasons which induce me to accept the derivatist doctrine, and to reject the creational fall, under the two heads of probahilities and conclusive evidence. The probabilities are cumulative in their pointings, and form part of a hody of evidence which is to my mind conclusive. The reasons why derivation is prohahle are the euccessional relation of increment or decrement of structure, observed in:

1. Systematic biology (taxonomy); 2. embryonic growth (emhryology); 3. in geologic time (paleontology); 4. and in the coincidence in the successions seen in Nos. 1, 2, and 3.

The fact that it is necessary to arrange animals in an order corresponding with the phases of tbeir emhryonic history is remarkahle; but the further fact, shown by paleontology, that the same succession marked the ages of past time, at once hriugs evolution within the limits of strong prohability. Nevertheless, all this might have heen a mere system, without tranеitions hetween its memhere; organic types might have heen created unchangeable, but presenting the mutual relations in question. But if transitions among these memhers can be shown to take place, then indeed the phenomena mentioned receive a sufficient explanation. They are seen to be the necessary relations of the parts of a shifting scene of progression and retrogression; they express combiuations of structure, which, though often long enduring, are, uevertheless, not perpetual, hut give way to other comhinatious to he in their turn dissolved. Now, if there is anything well known in nature, it is that there are divisions of various ranks in the vegetahle and animal kingdoms, whose contents preseut variations of structure which are confessedly additions to or suhtractions from the characters of ancestors, which have appeared during ordinary descent. The protean species, genera, etc., are well known to biologists, and every naturalist who admits varieties, suh-epecies, eub-genera, etc., admits derivation so far as they are concerned. The facts of variation, including "sporting," etc., are notorious, not only among domesticated, hut also in wild animals and plants. The facts have led some persons to euggest that epecies have been produced hy evolution from a single specific center, but that the genns and other comprehensive divisions are nnchangeable. But I think I have ehown, in a paper entitled "The Origin of Genera,"† that the struetural characters which define genera, and even higher divisione, are suhjects of variation, to as great an extent as are the less profound specific characters; and, moreover, that the evidence of derivation which they present is singularly clear and conclusive. The cbanges of hoth genus and species character are always of the nature of additions to or suhtractions from those of one generation, displayed hy their descendants. As euch, they form the closing chaptere of the emhryonic or growth-history of the later generation.

In order to explain more fully the application of the ahove statements, I introduce a few examples selected from the eubjects of my studies. Their number might he indefinitely extended. I first cite the genera of the tailless *Batrachia* (*anura;* frogs, toads, etc.), whose relations are very simple and clear, and show the parallelism between adnlt structure and emhryonic succession. See above, 1 and 2.

The greater number of *Batrachia anura* fall into two divisions, which differ only in the etructure of the lower portion of their scapular arch, or shoulder-girdle. In the one the opposite halves are capahle of movements which contract or expand the capacity of the thorax; in the other the opposite halves ahut against each other, so as to he incapahle of movemcnt, thus preserving the size of the thoracic cavity. But during the early stages, the frogs of this division have the movahle shoulder-girdle which characterizes those of the other division, the consolidation constituting a modification superadded in attaining maturity. Furthermore, young *anura* are toothless, and one section of the species with emhryonic shoulder-girdle, never acquire teeth. So here we have a group which is imperfect in two points instead of one. This is the tribe *Bufoniformia;* the trihe with teeth and emhryonic shoulder-girdle is called the *Arcifera*, and that which is advanced in both these respects is the *Raniformia*. Now the frogs of each of these divisions present a nearly similar scale of development of another part of the ekeleton, viz., the hones of the top of the skull. We find some in which one of these bones (ethmoid) is represented hy cartilage only, and the fronto-parietals and nasals are represented hy only a narrow strip of hone each. In the next type the ethmoid is ossified; in the next, we have either tbe fronto-parietal or nasal only eompletely ossified, usually the former; in the third form, hoth hones are completed. In the fourth station on the line, these hones are rough, with a hyperostosis of their surfaces; aud in the next set of speciea, this ossification fills the skin, which is thus no longer separahle from the cranial bones. In the last and seventh form, the ossification is extended so as to roof in the temporal muscles and enclose the orhits hehind. Now all of these types are not found in all of the families of the *Anura*, but the greater number of tbem are. Five principal families, three of which belong to the *Arcifera*, are named in the diagram below. I do not give tho names of the genera which are defined as ahove described, referring to puhlished systematic works for them, hut indicate them by the numbers on the margin of the page, whicb correspond to those of the definitione ahove given. A zero mark signifies the absence or non-discovery of generic type.

	Sternum embryonic.				Sternum complete.
	Bufoniformia.	Arcifera.			Raniformia.
	Bufonidæ.	Scaphiopidæ.	Cystignathidæ.	Hylidæ.	Ranidæ.
1—	0	0	1	1	0
2—	2	2	2	2	0
3—	3	0	3	0	3
4—	4	4	4	4	4
5—	5	5	0	5	5
6—	6	6	6	6	6
7—	7	7	7	7	0

It is evident, from what has preceded, that a perfecting of the shoulder-girdle in any of the species of the Bufoniform and Arciferous columns, would place it in the series of *Raniformia*. An accession of teeth in a species of the division *Bufoniformia*, would make it one of the *Arcifera;* while a small amount of change in the ossification of the hones of the skull would transfer a epecies from one to another of the generic stations represented hy the numhers of the columns from one to seven.

There are few groupe where this law of parallelism ie so readily observed among cotemporary types as in the *Batrachia*, hut it is none the less universal. The kind of parallelism usually observed is that in which there is only a partial resemhlauce hetween adults of certain animals aud the young of others. This has been termed "inexact parallelism," and the relation presented hy forms not very nearly phylogenetically related. The more remote the phylogenetic lines of two types, the more "inexact" will their parallelism he. It was once a question whether any parallelism could be traced hetween the members of the primary divisions of animals, and in my essay on the "Origin of Genera," I was compelled to state that there was then "no evidence of the community of origin of these divisions." Since that time, Haeckel has puhlished his "Gastræa Theory." This is a grand generalization from the facts of emhryology, which shows the community in type of the early stages of all animals, and the similarity of the phasee which they present during a part of their larval life.

The paleontology of the *Batrachia anura* is largely unknown, eo we must look elsewhere for proof of the truth of the fourth proposition, viz., that the successional relation in emhryology corresponds with that shown by paleontology to have existed in geologic time.

For this purpose I select one of the most complete series known to paleontology; that of the camels or *Camelidæ*, whose remains are found ahundantly in various parts of our country. The snccession of the known genera is seen in the structure of the bones of the feet, of the superior incisor, and premolar teeth. The metatarsal and metacarpal hones are or are not co-ossified into a cannon hone; the first and second superior incisor teeth are present, rudimental or wanting, and the premolars nnmher from four to one, The relation which these conditions hear to geologic time is displayed in the following table, commencing with the lowest horizon:

	No cannon bone.		Cannon bone present.	
	Incisor teeth present.		Incisors 1 & 2 wanting.	
	Four premolars.	3 prem'ls.	2 prem'ls.	1 prem'ls.
Lower Miocene.	*Poebrotherium.*			
Upper Miocene.	*Protolabis.*		*Procamelus.*	*Pliauchenia.*
Pliocene and Recent.			*Camelus.*	*Auchenia.*

This table shows that geological time has witnessed, in the history of the *Camelidæ*, the consolidation of the hones of the feet and a great reduction in the numhere of the incisor and premolar teeth. The emhryonic history of these parts is as follows: In the fœtal state all the *ruminantia* (to which the camels helong) have the cannon hones divided as in *Poebrotherium;* they exhihit also incisor teeth, ae in that genus and *Protolabis*. Very yonng camels have the additional premolar of *Pliauchenia*. They shed this tooth at an early period, hut very rarely a camel is found in which the tooth persists. The anterior premolar of the normal *Camelus* is in like manner found in the young lama (*Auchenia*), hut is shed long before the animal attains maturity. I may add that in some specimens of *Procamelus* caducous scales of enamel and dentine in shallow cavities represent the incisive dentition of *Protolabis*.

It remains to show that characters of the kind above mentioned are sometimes inconstant; tbat they may or may not appear in individuals of a species. Under such circumstances it is evident that their origin does not imply any break in the line of descent.

First, as to a family character. It is well known that the deer differ from the giraffes in the presence of a hurr or ring of osseous excrescences surrounding the hase of the horn. Now in the extinct tertiary genus *Procervulus* there are three species which possess or lack this burr indifferently. Why some individuals should, and others should not possese it, ie not kuown.

Second, as to a generic character. The genus *Canis* (dog) is defined hy the presence of two tuhercular morlars in the inferior series. The allied genus, *Thous*, possesses three euch teeth, while *Icticyon* has hut one. Now examples of *Canis familiaris* (domestic dog) with hut one tuhercular molar are not rare, while an individual with three is occasionally found.

To take another case. The normal dentition of *Homo* (man) is, on each side, incisors, 2; canine, 1; premolars, 2; molars, 3. It is very common to find in the higher races, individuals who have molars only two in one or both jaws; and the absence of the external incisors of the upper jaw is almost as frequently met with. Here we have two new generic variations in one and the eame species.

In specific charactere variations are most familiar. Thus, the young of deer are generally spotted, and the adults are nearly uniform in coloration. Some deer (as the *Axis*) retain the spotted coloration throughout life, while au occasional spotted individual of unicolor species, is a violation of specific character by a failure to develop. The larvæ of some salamanders are of uniform coloration, and the adults spotted. The unicolor adults of tbe same species, not uncommonly met with, present examples of the same kind of variation.

Any biologist can select hundreds of similar cases from his epecial department of study.

II.—The Laws of Evolution.

Having reviewed the reasons why the doctrine of evolution should he received as truth, I desire to give atteution to the lawe which may be made out hy reference to its phenomena. Progress in this direction is difficult, owing to the natural impediments in the way of studying the history of the growth of living heings. We will, however, commence hy examining more fully the phenomona with which we have to deal.

It is well understood that the world of animal life is a uicely adjusted equilihrium, maintained between each individual and its environment. This environment consists of hoth purely physical forces and those exercised hy other animals. Animals antagonize each other in procuring food, whether that food consist of vegetation or of other animals, hut in the latter case the conflict is more severe. A similar competition exists among male animals in the matter of reproduction. These exhibitions of energy constitute tbe struggle for existence, which is the daily husiness of the living world. It is well understood, that in this struggle the individuals best provided with means of self-preservation necessarily survive, while the weak in resources must disappear from the ecene. Hence those which survive must display some especial fitness for existence under the circumstances of their environment, whatever they may he. So the "survival of the fittest" is helieved to he a law of evolution, and the proccss hy which it is brought ahout has been termed "natural selection."‡ The works of Darwin and others have satisfied biologists that this is a *vera causa*.

Before the excellence of a machine can he tested, it muet exist, aud hefore man or nature selects the best, there must he at least two to choose from as alternatives. Furthermore it ie exceedingly improhable that the nicely adapted machinery of animals should have come into existence without the operation of causes leading directly to that end. The doctrines of "selection" and "snrvival" plainly do not reach the kernel of evolution, which is, as I have long since pointed out, the question of "the origin of the fittest." The omission of this problem from the discussion of evolution, is to leave Hamlet out of the play to which he has given the name. The law by which structures originate is one thing; those hy which they are restricted, directed, or destroyed, is another thing.

There are two kinds of evolution, progressive and retrogressive; or, to use expressions more free from objection, hy addition of parts and hy suhtraction of parts. It is further evident that that animal which adds something to ite structure which its parents did not possess, has grown more than they; while that which does not attain to all the characteristics of its ancestors has grown less than they. To express the change in the growth-history which constitutes the beginning of evolution, I have employed the terms "acceleration and retardation." Generally these expressions are literally exact, *i.* e., there is an increased rate of growth in evolution hy addition, and a decreascd ratc in evolution by subtraction; hut this is not always the case, for some divisions of animals have increased the length of their growth-period without reference to evolution in structure. The terms express the phenomena figuratively, where not exact in the sense of time, and I believe they are sufficiently clear. The origin of the fittest is then a result of either accelcration or retardation. It is easy to perceive that a character which makes its appearance in a parent hefore or near to the hreeding season is likely to he transmitted to its descendants; so also a character which is lost near

MECHANICAL PROGRESS.

The Steel Age.

Every day steel is supplanting iron for some one of the numerous purposes to which that metal has hitherto been applied. Iron rails are alrsady replaced, or soon will bs, by steel rails on svery considorable railwsy in tho land. In a paper read before the Iron and Steel Iostitute, it was stated that many of tho British lines could not have paid more thau half the dividenda they now make if it had not been fer the development of steel rails and steal tires. The opiuion is gaiuing ground among ahipbuilders that a framework of ateel for vessels would be superior to iron, being a lightor material in proportion to its atreugth. It is evidcnt that tho coming century is to ho an age of stcel. Upon the perfection of that metal, and its adaptability to the various usea to which it may be put, the safcty of tho modern traveler must largely depend. And whether he is rushing ever the surface of the earth on an cxpress train at the ratc of 50 miles an hour, or driving 350 miles a day through the ocean on a transatlantic steamer, he wants to rest assured that scienco has dono all it can to make his journey safe.

The abovo remarks were suggested by the opinion expressed recently at the Iron and Steel Institutc in Liverpool, that the tests reqnired at present for steel were too stringent and severe. But it was answered that the traveler would not feel as safe as he does were the tests of steel diminished in severity. Criticism was chiefly directed to the tests applied by the Lloyds and the Admiralty to steel used in shipbuilding only; but it is probable that if stringency is relaxed in one direction, it will be in all. The argument was that although steel makes a better framework for ahips than iron, it will not he employed at present, becauso it mnst undergo tests proportionately mucli more severe than those to whieh iron is subjected. In other words, the mannfacturers, or some of them, contend that under much lighter tests than those now required, steel framework would be quite as strong as the iron framework which the authorities constantly approve. But this may be an argument against the suffieiency of the iron tests, rather than against the stringency of the steel tests.

Whether it is or not, however, Dr. Siemens, than whom no man ought to be more competent to speak on the aubject, pointed out a difference between iron and steel which appears to justify the maintenance of the severest tests. Iron, he said, always holds together, except when fractured hy a blow under peeuliar circumstances; its tendency is to hold together when struck or strained, whether it is of good or poor quality. But this is not the case with all steol. The hest steel, it is trus, will bend like leather rather than break, but anything inferior to that quality is far more liable to disastrous fracture than iron. Hence, said Dr. Siemens, do not diminish the tests of steel, bnt rather increase their severity.

Practically, this positive expression of opinion from so high an authority settles the question for the time heing. We do not mean that there was no dissension from the views of Dr. Siemens, hut none of the steel tests under consideration are likely to be relaxed in opposition to his emphatic advice. As the maintenance of a high standard of excellence in Great Britain is conducive to the maintenance of a like standard in this country, we regard this result with content.—*Manufacturer and Builder.*

Manufacture of Iron and Steel.

In working those gradea of iron and steel which are reduced to a fluid condition in being converted directly or indirectly from pig-iron, Mr. E. Whceler, of Philadelphia, proposes to nse a malleahle metal casing of a shape adapted to the form of product required. The thicknesa of material of which the mold is made must be determined largely by the nature of the product. In any case the material must he strong enough, and the joints, aogles, or corners of the mold must he tight enough to retain the molten contents, not only when they are poured into the mold, but also during subsequent treatment or working. One end or side of the mold should be made removable for the purpose of filling, or in lieu thereof a snitable opening should be made in one of the sides or ends of the mold. If a product is required having substantially a uniform quality throughout, the mold is filled with the desired metal while the latter is in a molten condition by pouring or in any other convenient way. It is not essential that the mold be filled at one pouring, or while all the contents of the mold are molten, the metal, for instance, may he poured in from time to time, until the desired quantity is obtained.

If it is desired to mix a certain proportion of iron or steel, whether fibrous or cast with homogeneous metal, it may be first arranged in the mold as desired, and molten metal poured in so as to fill the interstices between the solid portions and complete the filling of the mold to the extent desired, or the mold may be partially filled with metal of one grade, and metal of another grade be subsequently added, thus forming an ingot in which different gradcs of metal are arranged either miscellaneoosly or rsgularly in separate layers or divisions, tho arrangement depending upon the charscter of the product required. When thus filled, ths opening in tho mold is closed by any suitable cap, cover, or stopper, the latter being sscured by riveting, welding, banding, or otherwise, so as to confine the contents of the mold during subsequent working. The meld and contents are then placed in a suitable heating furnscs and raised to such temperature that the homogenssons or cast portion of tho contents shall be eithor in whols or in part in s ststo of fusion or semi-fusion. This can readily hs dons without destroying the form or shape of the mnld or casing, since the degrco of hcat at which wrought-iron fusea or becomes liquid is much higher than that at which homogoneous irou fuses, and still higher than that at which steel fuses. In the operation tho mold or casing operates substantially as a cruciblo, retsining the contsnts and excluding tho air.—*Coal Trade Journal.*

Monster Steamers.

It seems that the Central Pacific ferry steamer *Solano*, now the largest ferry boat in the world, is about to be eclipsed by an English ferry boat which will soon be constructed for crossing tho British channel. The *Solano* is but 424 feet in length, while the English boat is to bo 650 feet long. The breadth of beam of the *Solano* is 116 feet, while that of the English boat is to he 150. The English hoat will be used like the *Solano*, for transporting railroad trains, and will be propelled by a number of paddles and screws, and will form a connection with the railroads running from the coasts to London and Paris. A movable platform on an incline will connect the ferry and the shore rails. This monster will be as long as the *Great Eastern*, and more than twice her width.

The managers of the Inman line of steamers are also building a monster steamer to run between New York and Liverpool. She will be known as the *City of Rome*. Her dimensions are to bc as follows: Length of keel, 546 feet; length over all, 590 feet; breadth of beam, 52 feet; depth of hold, 38 feet 9 inches, and depth from top of deck-houses to keel, 52 feet. Her measurement will he 8,300 tons, or over 2,000 tons larger than either the *City of Berlin* or the *Arizona*. She will be over four-fifths of the size of the *Great Eastern*. The enginea will he of 8,500 horse power, with six cylinders, three of which are high-pressure and three low-pressure. There will ho eight boilers, heated by 48 furnaces, and the vessel can be propelled at a rate of 18½ knots an hour. She will carry four large masts and three smoke funnels. A large spread of canvas can he set, which will enable the steamship to make good time, if necssary without the aid of the engines. She will be built of steel, with a double bottom, and eleven bulkheads. Two longitudinal hulkheads are to he run through the engines' and boilers' space. These will greatly decrease the danger of the vessel sinking in case of a collision. The top decks are to be of the hest teak. No expense is to be spared in making this magnificent steamship perfect in every respect. She will have the highest classification of any vessel in the Liverpool Red-book and in the British Lloyds. The Inman people expect that the *City of Rome* will prove the monarch of the seas.

Phosphorus Needed in White Pig Iron.—The *Journal de Liege* publishes the following remarkahle statement as to experiments being made in the Horde Works in Germany: Instead of blowing gray pig rich in silicon, it was found possible to treat white pig, if it contained a sufficient amount of phosphorus. Far from being afraid of phosphorus, some 2% of that body is required in the pig, in order to give a sufficient degree of heat to the bath. Horde has begun to make ferrophosphide with 20% of phosphorus, and will presently make this alloy to contain 50% phosphorus. This will be sold to mix with white pig, since the crude metal must contain phosphorus or silicon enough to carry up the hath to the heat required. At Horde all sorts of pig, even cinder pig, with 3% phosphorus and 0.5% silicon, were treated. The presence of 0.2% to 0.3% sulphur could also, it was found, be tolerated. The steel made contained under 0.1 phosphorus and no silicon. On Decemher 1st, experiments of a character recognized as decisive were carried out before a party of ironmasters assembled to watch the operations.

Oxidation of Iron and Steel when in Contact.—Mr. G. Radcliffe, in a paper read before the Iron and Steel Institute of Great Britain, incideutally mentioned a case in which steel boiler plates, which had been exposed to the same conditions as adjacent iron plates, had distinguished themselves by pitting more than the latter. The steel plate next to the iron one was oxidized considerably more than any other. This fact would appear to point to a species of galvanic action set up by the contact of the two varieties of metal in an exciting liquid, the steel playing the part of the positive element. Mr. Radcliffe does not attempt, however, to offer an explanation, hut simply concludes that, under the above-named circumstances, it will not do to place iron and steel side by side.

Straightening Hardened Steel.—In hardening and tempering tools they sometimes spring, to the great annoyance of the workmen, and not seldom the tool is reheated and rehardened. In most cases this may be avoided. To straightsn a piecs of steel already hardened snd tempered, heat it lightly, not enough to drsw the temper, and it may be straightened hy hlows from a hammer, if the charscter of the tool will admit of such treatment, or, as in case of a tap, it may be straightened hy a hcavy mallet on a bard wood block. Although ths steel when cold would break like glass with this treatment, when slightly warmed it will yield to moderatsly heavy hlows uniojured.

SCIENTIFIC PROGRESS.

The Desert of Sahara.

Much attention is now being sttracted to the great African desert, Sahara; not altogether through more motives of curiosity, but chiefly in the interest of science, and with the view to flooding somo portions of that region and bringing others into more favorable conditions for cultivation. Two plans for flooding have been suggestsd, one to let in the waters of the Mediterranean and make a sea of the lower portions; the other is a more gradual but eqnally sure and more serviceable mode of improvement, by which fresh water may spread its fertilizing influence over a large portion of those now drear and arid plains.

It is well known that even within historic times, Sahara has been a comparatively fertile and popnlous region. Its ancient fertility was not derived from rivers, but from wells, "spouting wells," they were called then, which from disuse or other cause have long since ceased to flow. So that the very existence or even possibility of such wells, anywhere, had been almost or quite forgotten until within a few years, when similar wells, now known as artesian, were found in the Valley of the Seine, from whence their knowledge and use has apread over almost the whole civilized world.

That artesian wells once existed among the oases of the Sahara desert is known from what is said of this region by ancient writsrs. References in this direction are given by Lieut. Schroeder, U. S. N., in a paper in the last number of the *Popular Science Monthly*, from which we condense a few paragraphs:

Diodoras, a priest of Tarsus, 1,600 years ago spoke of the great oasis, 40 leagues from the Egyptian frontier, which he said was irrigated, not hy rains or rivers, hut by springs which issue continually from the ground,—not spontaneously, but by great labor on the part of the inhabitants—meaning, of course, artesian wells, bored or in aome way sunk by man. Some of these old wells have been discovered within a few years, and found filled with stone valves, by which their flow could be regnlated. Some of these wells are spoken of by other ancient writers as being 500 cubits deep. How they were dug will probably ever remain a mystery. Several Arabian writers spoke of them over 1,000 years ago, as then flowing. Ibn Khaldoun referred to them as "spouting wells," and coosidered them a miraculous fact. Their origin had even then been lost. Modern research has disclosed the sources of supply of these artesian waters, which atill exists in numerous localities all along the eastern and northern borders of that great desert region.

Although our knowledge of its geology and hydrography is as yet quite meager, enongh is known to determine that immense subterranean sheets of water may he found in many places at a comparatively small depth from the surface; and it is quite certain that if an enterprising and energetic people were planted upon the hordera of this desert, in place of the bigoted, lazy Saharan tribes who now roam upon them, the desert would soon again become clothed with verdure, and be made a most productive country. It is a curious but well attested fact that many ancient wells have been filled up hy the more recent dwellers, evidently either for the purpose of defence against warlike invasion, or with the view of discouraging the influx of a more energetic and industriona class of people than themselves.

The French have already commenced a system of improvement in the desert back of Algiers. The first artesian well was struck as long ago as June, 1856. Within the next eight years seventy-two successful borings had been completed, the deepest of which is only 364 feet. The supply of water is exceedingly abundant, and of most excellent quality.

Origin of the Desert.

The writer, above alluded to, also gives the following as a possible hint at what may have greatly aided in the change which has converted this once prosperous and comparatively fertile region to its present sterile character:

A M. Largeau in 1874 visited the Valley of the Igharghar, with the intention of branching off to Rhadames to study the commerce of that oasis and test the practicability of diverting to Algeria the caravans that come there by the central routs from Soodan. He questioned the *chambas* on the causes of the drying of the great Saharan streams, and found that all agreed in saying that these dead rivers once ran full through a country more fertile than the Tell (the region north of the Atlas mountain's crest), but conld only explain it by legends more interesting than satisfactory.

M. Largeau gives the following explanation of the change: "It is knewn that pastoral people have always been great destroyers of forests, for they need large spaces of clear ground to feed the flocks that form their wealth and to promote security against the wild beasts that lurk in forests. Evsn now the Algerian Arabs srs sesn firiog the woods to enlargs the narrow limits imposed upon thsm by colonizstion. So, although the great Saharan strssms have not bean explored to their sources, yet it is known that they commence on the bare plateaux that are but the skeletons of hights once wooded and fertile. All accounts of the inhabitants of these regions agree on that point. Consequsnt upon the destruction of the forests the periodical rains were replsced by rare snd short though violent storms, the waters from which, instead of soaking in as in past ages, slip by on the rocky masses, carrying away the rich surface mold, and bring about the drying of the springs, and, as a direct consequence, of tho rivers."

A New Bleaching Process.

A new process of bleaching by means of nascent oxygen (ozone), which promises to effect great changes, especially in the employment of chloride of lime, has been discovered by a French chemist, M. Dienheim Brochocki, of Paris. In bleaching with chlorine in the ordinary manner the material to he treated is brought into direct contact with the bleaching agent, whether it consists of dry chlorine gas, or of an aqueous solution of hypochlorite of lime. In the former process the chlorine destroys the coloring matter by combining with its hydrogen, forming hydrochloric acid, which, as fast as it is formed, acts destructively upon the ligneous matter, and the mass cannot he entirely bleached without being destroyed to a great extent.

In the other case the hypochlorous acid of the chloride of lime is too intimately combined with its base to have any great tendency to combine with the hydrogen of the coloring matter, and it is only hy the addition of an acid, which displaces it from its base, that it is rendered active. The result is a loss in hypochlorous acid which escapes from the mass, an immediate injurious effect upon the fiber caused by the acid added, and a more or less slow destructive action due to the lime, which becomes incrusted in the pores of the fibers in the form of insoluble salts, incapable of being entirely removed by washing. A new compound, "chlorozone," it is claimed, obviates these objections. The chlorozone may he acid or alkaline, liquid or solid. It is in either case obtained in the cold by saturating a caustic alkaline lye by a current of hypochlorous acid in conjunction with a current of air.

The rationale of its action may be thus explained: Chlorozone being a compound of soda and a loose chloric acid, with an excess of caustic soda in the solution, when the cloth is put into the bath the chloric acid is broken up, the oxygen combining with the hydrogen of the coloring matter to form water, while the liberated atom of chlorine is taken up by the free caustic soda, and forms chloride of sodium, or common salt, setting free in its turn another atom of the hydrogen in the coloring matter. These compounds all being soluble, are held in solution in excess of the water present. The oxygen set free being in a nascent condition (ozone), is one of the most powerful bleaching agents known.—*Paper World.*

Refinement in Experiments with Falling Bodies.—Waldron, of Strasburg, has invented several new methods of demonstrating practically the laws to which falling bodies are subject. One of his instruments consists of a small metallic hall suspended by a string and under it, at a distance which we will call 1, are a pair of metallic balls connected with the poles of an electric machine, and so far apart that no spark can pass, but so near that when the suspended ball falls between them a spark will pass. Directly under this are several other pairs, similarly arranged, at distance of 3, 5, 7, etc., all connected with the electric machine and in the same circuit. When the thread of the suspended ball is burned, the ball falls between the others under it, giving passage, at each pair to the current; and a simultaneous spark in another part of the circuit makes a mark for each pair of balls, on a revolving blackened cylinder or disk. The intervals between the marks are found to be equal, which proves that when the time occupied by a falling body is divided into equal periods, it falls during the first period 1 distance, during the second it will pass over 3, during the third 5, and during the fourth period 7 such distances.

The Passivity of Iron.—M. Louis Varenne recently examined the passivity of iron when employed as the positive pole of a nitric acid battery, or as positive electrode of a voltameter cell containing nitric acid, and concludes that the passive state is due to a film of nitric peroxide which collects upon the surface of the iron and protects it from further chemical action. M. Varenne states that this film is apparent when the surface is examined under the microscope. He finds that the passive state ceases if a stream of carbonic dioxide or of hydrogen is passed through the liquid, and that solution proceeds apace. He also finds that nitric peroxide gas is evolved from the passive iron when it is placed in vacuo.

Mining Share Market.

The week has been without any movement of note. There has been but little business transacted and nothing to break the monotony in the way of either sudden advance or reduction in prices. The fluctuations have been limited, leaving but little margin of profit to operators.

The usual amount of bullion is coming in from the mines, with a steady increase as the opening of them progresses.

The Alabama and Humboldt Con. M. Co. have declared a stock dividend of 50%.

Mr. Gorley has presented a hill to the State Assembly, prohibiting brokers from loaning the stocks of their customers, left in their hands, and compelling them to return the identical shares when the stock is called for. It meets with general favor from the stock-dealing public.

All attempts to advance prices have been followed by such a speedy unloading by holders to realize, that the market has been forced to yield to the pressure.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Gold Hill (Idaho), Jan. 17, $24,497; Standard, Jan. 19, $21,293.27; Northern Belle, Jan. 19, $10,775.77; Jan. 21, $6,182.01; Star, Jan. 21, $6,800; Hillside, Jan. 22, $6,000; Paradise, Jan. 21, $2,500; Jan. 23, $4,151; Argenta, Jan. 21, $4,910.69; Jan. 26, $16,300; Con. Virginia, Jan. 22, in January to date, $92,703.70; Jan. 24, $43,357.05; California M. Co., Jan. 22, in January to date, $106,814.07; Wells Fargo & Co. at Eureka, Jan. 21, $8,532.75; Jan 24, $5,588.28; Eureka Con., Jan. 21, 32,450 lbs.; Jan. 22, 31,400 lbs.; Jan. 24, two days, 68,860 lbs.; Christie, Jan. 23, $6,195; Union, Jan. 24, $24,835.38; Richmond, Jan. 24, $16,490.40; Belmont, Jan. 19, $2,332.75; Jan. 23, $2,551.97; Ivanpah Con. M. & M. Co., Jan. 23, $9,000; Leopard, Jan. 20, $2,250; Jan. 26, $1,960; Bodie Con., Jan. 27, $14,927.

GRAPHITE AXLE GREASE.—Dixon's American graphite everlasting axle grease, advertised in another column, is now in use in a number of places in this city, both on journals of machinery and on axles of wagons. It is equally useful for light wagons, family carriages or loaded teams, and in fact is adapted for all kinds of journals. It is made from pure Ticonderoga graphite. The old mines formerly worked and the new deposit at Ticonderoga, N. Y., utilized. The J. Dixon Crucible Co., of Jersey City, N. Y., also prepare pure foliated American graphite, which is a perfect lubricator, being entirely free from grit when prepared by the improved Dixon water process. Mixed with oil or grease it is claimed to positively cure hot journals, steps of mills and all troublesome bearings, saving them from much wear and causing them to run easier. Mr. Warren Holt, 717 Montgomery street, agent for the lubricator for this coast, has shown us samples of the foliated lubricator, and examination shows it to be pure and free from all grit. It is put up in small paper cases, tin cans and boxes according to quantity.

ATLANTA CO.'S MINE.—The Atlanta Co.'s mine is located in West Tintic mining district, Juah county, Utah. Those who have seen the mine say that the ore resembles that of the Great Ontario, which has paid its millions in dividends. Utah properties generally are first class. The Atlanta's first assessment of five cents per share will be delinquent February 5th, 1880. The company has been in existence but two years, and has been an example on light assessments.

THE residence owned by Governor Perkins in this city has been sold to John D. Spreckles, for $21,250.

THE extension of the Western Oregon railroad has reached Corvallis.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

MINING NOTES.—Amador *Ledger*, Jan. 24: A. McMahon and Isaac Eastman have seemingly struck it rich about half a mile from Peter Denizer's, three miles east of Volcano. They had been prospecting in the neighborhood for a few days, and a week ago came upon a quartz vein in the locality indicated, which, to say the least, is big, with promise of wealth. The prospect hole has been sunk 14 ft; and the vein of ore at the bottom is 10 inches wide, the ledge uniformly widening as the depth increases. Specimens from this discovery were exhibited in Amador City on Wednesday, and the best judges of quartz there gave it as their opinion that rock of that character would yield $100 per ton. A quarter of a pound of quartz in which no free gold was visible, was pounded up, and surrounded nearly a quarter of a dollar in gold. No gravel mining is going on at present. The water remains frozen in the ditches. Col. Heath has thrown up his contract on the big tunnel. The tunnel company have the work in hand now, with Mr. Moyle superintending the operations.

NORTH GOVER.—The drift has been run 40 ft on the last contract. There is a small vein of white quartz 18 inches wide, which carries little or no gold.

DEWITT.—This claim at Murphy's ridge has been put in excellent running order. A ditch has been dug, 204 rods, to connect with the Moore ditch. A flume, 1,320 ft long, connects with the ditch and carries the water to the summit of the ridge. The ditch is constructed to carry 300 inches of water, but not more than 125 inches will be required on the claim. Water has been turned into it, and mining operations on a large scale may be carried on right over the ridge. The ditch and flume cost $700. Two hundred ft of new pipe is expected in a few days, when everything will be in readiness to commence washing. From rock taken from strata of decomposed quartz, Dewitt has pounded out by hand mortar, something like $5,000 since May last.

OTHER MINES.—The Lincoln mine and mill give employment to 80 men. Report says that the 40 stamps of the Con. Amador mill are to be started up shortly. The rock is low grade, and it is only by getting through a large quantity that it can be made to pay. The prospect is fair for the ledge to improve in quality as depth is attained. The operations at Butte Basin are confined to taking out the water. The Amador Gravel company are preparing a blast that will consume 5,000 pounds of powder. They expect to fire it on Monday next.

BUTTE.

BUCHANAN HILL.—Oroville *Mercury*, Jan. 23: Work has been resumed, and a new gravel pulverizer will be erected soon.

HENDRICKS.—Things are in full blast, and the prospect of good returns is favorable. They are working upon new ground further down the ravine.

CALAVERAS.

BOSTON.—Calaveras *Chronicle*, Jan. 24: Col. Robinson, Superintendent of the Boston, showed us some fine specimens from that mine lately. The rock showed rich in free gold and sulphurets. The developments at the Boston are altogether favorable, and the prospects that the mine will prove a valuable one are flattering in the extreme.

MONO.

STANDARD CON.—Bodie *Free Press*, Jan. 20: The north drift, 385 level, is in from the main east crosscut 635 ft. The ledge in this drift is four ft wide of good ore. The upraise from this drift is 30 ft above the level, showing a ledge five ft wide of good milling ore. The south drift is in 305 ft, with a ledge in the face three and a half ft wide of fine ore. The upraise from this drift is 29 ft. The ledge is three ft wide and looks well. The east crosscut, 500 level, is in 170 ft. The crosscuts on the 700 level are making the usual progress. The east crosscut is in a very favorable formation. In the west crosscut the rock is very hard. The shaft has reached a depth of 55 ft below the 700 level. The rock in the bottom is very hard. The north drift on the east ledge, 300 level incline, is in 210 ft, showing a ledge two ft wide of good milling ore. The south drift from the west crosscut, 300 level incline, is in 135 ft. The ledge in this drift is three ft wide of good ore. The ledge in the stopes, north drift, 335 level, is from 12 to 20 wide ft of good grade ore. In the south drift, 550 level, the stopes are looking well, the ledge being 10 ft wide of good milling ore. The West Standard is looking well. The ledge is five ft wide of rich ore.

BELVIDERE.—The east crosscut, 400 level, is in 35 ft; the ground is a little softer and works better. This hard belt of rock has either carried the ledge further to the east than was expected, or there has been a break in the ledge which carried it back in the shaft, so changed in its character and appearance that it was not recognized. In order to hasten the solution of the problem, drifts have been started north and south on the ledge in the station, from which an upraise will be run to the point where the rich ore is known to exist, say 30 ft above, that is, should this ledge prove to be the main ledge which had run in the shaft for nearly 60 ft between the 300 and 400 levels. In the latter case the drifts north and south will be continued in the belief that the rich ore chimney will make downward in one direction or the other, or both, for it is likely that this station is in a broken portion of the ledge.

JUPITER.—The tank stations at the 200 and 400 levels and bob-pit at the 250 level are nearly completed, as well as the tanks. The boilers will be put into position. More or less delay has been occasioned by storms in getting in some portions of the timbers and lumber, but all is now plain sailing. The last of the engine foundation timber has now on the ground, as well as everything required except the plunger pumps for the 400 station and a portion of the pump-rod. On account of the work in the shaft, work has not yet been resumed on the 500 level, but will be shortly.

BULWER CON.—The north drift on the Stonewall ledge, 480 level, is in 22 ft. The ledge is 18 inches wide, and looking well. The south drift is in 28 ft, showing a ledge two ft wide of good ore. The north drift from the tunnel on the Ralston ledge is in 10 ft. The ledge is three and a half ft wide of good milling ore. The south drift is in 23 ft, with a ledge in the face two and a half ft wide. The west crosscut from the 100 level of the Bodie mine is in 93 ft, and during the past week cut through a ledge three ft wide of good milling ore.

GOONSHAW.—The shaft has now attained a depth of 553 ft. A few days since a very strong flow of water was encountered. The pumping machinery is working splendidly, but is not working to its full capacity. The shaft is being sunk rapidly. As soon as the 600 level is reached the company will crosscut for the ledges which are prospected on the 450.

BOOKER CON.—The new plunger pump, No. 2, is at work, and the sinking pump has been disconnected, but is in place, ready to resume sinking at any time. The crosscut east, 480 level, is in 30 ft. The east crosscut, 400 level, is in 110 ft. Several stringers have been cut in the bottom. The vein should be cut in about 40 ft from the face of this crosscut. Everything is working well.

BODIE TUNNEL.—Work is progressing. Within the past two weeks three ledges have been cut, of very good milling ore. As soon as the roads are in fit condition to move lumber, the company will put up the machinery at the mouth of the tunnel for the purpose of running Burleigh drills in the face and to ventilate the mine.

ORIGINAL SUMMIT.—This claim is located on the west side of High Peak hill. The vein is not large, but is very rich, and may be found to increase in size on attaining depth. An incline shaft is down on the vein 105 ft. A drift will be run on the vein. Two shifts are kept constantly at work.

DOUBLE STANDARD.—The north drift from the east crosscut, 200 level, been run since last report, 11 ft; total length, 77 ft. The rock is somewhat harder. The south drift, same level, is now in 78 ft; progress for the week, 11 ft, with no change to note.

SUMMIT.—The north drift, 530 level, is in 49 ft; progress since last report, 12 ft. The ledge in this drift is three and a half ft wide, and looks well. The south drift has been extended during the past week, 11 ft; total length, 50 ft, showing a ledge two ft wide.

DUDLEY.—The main west crosscut, 500 level, is in 100 ft; progress, five ft per day. The favorable ground mentioned in last report still continues without material change. The pumps and machinery are all working well.

SOUTH STANDARD.—Timbering shaft with square sets from the surface to the 400 level is now nearly completed. It will then be level with the Booker, and when this is finished the surface will be ready for machinery.

HARRINGTON.—Bodie *News*, Jan. 22: The tunnel has reached a total length of 650 ft, and a winze is sunk 80 ft from the face of the tunnel, to a depth of 63 ft, showing a ledge three ft in width of good milling rock. There is a seepage of water, but work is not retarded. The ledge pitches to the east an angle of 80°, and will intersect the La Grange and Cronise ledges at a depth of 150 ft from bed of the tunnel.

ADDENDA.—During the week past they have been busily engaged moving the machinery from the old shaft to the new three-compartment shaft, preparatory to commence sinking by steam. All the machinery has been transferred and will at once be placed in position and hoisting commenced early next week, should no accident occur in the meantime. The new shaft has been sunk to a depth of 124 ft, and will be pushed rapidly down as soon as everything is in readiness for that purpose. The building over the new shaft is nearly completed and will be finished at an early date, when it will compare favorably both as to appearance and usefulness with any works on the lode.

CHAMPION.—Excavating is going on outside of the main building for the reception of the boilers. The main building is 80 ft in length, with the addition of boiler house and carpenter shop on either side. All the masonry for the bed, on which the new engine and boiler will rest, has been completed, and everything made ready to put the pumping gear in place. The foundation for the engine and pump is 50 ft in length, and is of the most substantial character. Men are at work in the shaft cutting out stations, one at 400 ft and the other at 200, for the pumps when ready to be placed. The pumping engine is compound, with 19x26-inch cylinder, has five-ft stroke, and is similar in character to the Cornish pumps in use, and a *fac simile* of the one now at work in the Julia mine on the Comstock. This pump is one of the cheapest and best in use, and will throw a large volume of water. Work is being done below ground in clearing out the east crosscut to the winze.

A mine owned by Charles Fisher (the name of which we did not ascertain) is also turning out ore, which yields largely—2,400 pounds having just returned 131 ounces. Campbell No. 2 shows an immense body of ore, and the owners are pushing work vigorously, taking out about four tons per day. It is thought that this ore will work up to 150 ounces to the ton. Nolson's mill is crowded with Georgetown ore, and the returns are giving entire satisfaction. The great lack of the district, and in fact the entire country, is adequate milling facilities. A large custom mill at Lone Mountain could be kept constantly supplied with ore, and under proper management would yield a large income to its owners.

NEVADA.

NONE SUCH.—Grass Valley *Union*, Jan. 23: This is a prospecting operation, near the lower Colfax road, about six miles from town, in the hills bordering Dry creek, and is being carried on by C. W. Smith and Milton Green, who have a shaft down about 20 ft, which is showing very heavy sulphureted ore that assays well in both gold and silver. The ore is peculiar in appearance, and from this fact the location takes its name, as "none such" has been found before in this section of the country. Although the shaft has reached but its present depth, the ledge is well defined and strong, and the owners feel encouraged to believe they have a rich mineral-bearing vein.

IDAHO.—The shaft of this mine has reached a depth of 80 ft below the No. 11 level, or a total depth of over 1,250 ft, showing a strong ledge of quartz.

DEADWOOD.—Grass Valley *Foothill Tidings*, Jan. 24: A nugget, valued at $200, was taken from the gravel claim of ex-Assemblyman Blackwell, at Snow Point, last week.

AMERICAN.—North San Juan *Independent*, Jan. 24: A blast, the largest ever fired on the ridge, was exploded Saturday evening last. Five hundred cases of Judson powder were used, equal to 25,000 pounds or 12½ tons. The main powder drift was 80 ft in length. There were also two other drifts run from either side the main drifts, making the whole the shape of a T. One of the side drifts was 67 ft long while the other was 60 ft. The shock occasioned by the explosion was so great at this place as to frighten people. A vast amount of ground has been pulverized by the blast, and excellent things are expected to result from its success. It has not been till recently that the mine has paid anything above expenses, but the last two clean-ups have proved conclusively that rich ground is being approached. The American mine owners have proved themselves a plucky set of men, and have surmounted great obstacles.

RICH STRIKE.—Nevada City *Transcript*, Jan. 24: One of the richest finds in the way of quartz that has occurred in this locality for many a day, was brought to light yesterday. Mr. E. Herring, who resides near Campooda, while out prospecting recently, came upon a ledge which had indications of being gold bearing. After sinking on it for a short distance, and picking out pieces of quartz from the lead, which varies in thickness from 12 to 18 inches, he found a strata running through the center of it, about four inches thick, literally filled with fine gold. One piece, weighing half a pound, Mr. Herring was offered $20 for, but refused it. A larger piece, weighing about two pounds, was valued at nearly $100. The exact locality of the rich strike is at present kept a secret, but a number of our gold hunters went out yesterday to try and find it, in order to stake off an extension.

HAYWARDS.—Washing was to have been recommenced at Hayward's claim, Dutch Flat, a couple of days since, the breaks in the ditch having been repaired.

BLUE TENT CON.—The Blue Tent Con. mining company resumed washing Friday morning with 1,000 inches of water. Operations had been suspended ever since the big snow storm of a couple of weeks ago, which had shut off the water supply.

NORTH BLOOMFIELD.—The North Bloomfield gravel mining company have succeeded in opening their ditch, and are at work again, after a rest of a few days. The electric light lately erected in their mine is an assured success.

MERRIMAC.—In this drift claim, which is situated adjoining the Round Mountain, in this township, gravel, carrying large quantities of a yellow metal, supposed by the owners to be copper, has been struck. Assays have been made showing the material to be gold, and the large deposits of gravel contain enough of it to pay abundantly for working.

MINING ITEMS.—Nevada City *Herald*, Jan. 24: The El Capitan mine is having new eight-inch pumps made for each of their claims. The Merrimac mine was the scene of great excitement this morning. Some rich prospects were struck. Mining at Sailor Flat is at present at a standstill, on account of the ditches being frozen. The Round Mountain mine is working on a 10-ft body of good pay gravel. The Deadwood mine is now crushing 300 tons of good rock. It is the largest crushing ever made by that mine. The Lord mine, which has been idle for some time, has again resumed work. There is already a tunnel driven in 700 ft. This mine has a three-ft ledge, and is in gold-bearing quartz. The above mine is situated on the Newtown road. The Buelow mine has stopped sinking the shaft and has commenced tunneling from the south side of the Yuba. The ore taken out at this place looks fine, and the owner feels highly elated over this discovery. The mine being close to the Excelsior ditch, the cost of running a mill would be slight. The Sargent & Jacobs mine, at Quaker hill, has sunk a shaft 200 ft and drifted 550 ft to center of channel. On the 1st of October they started to sink a new shaft to reach this point. Connection was made last Monday evening after reaching a depth of 180 ft. It will be necessary to sink the shaft some distance further to bedrock before taking out gravel. Daniel Oetchell, D. Rescigh and A. Turner, are taking out some splendid rock from their mine near Canada hill. The mine of Snider & Co. has a bright outlook. An assay gave $40.50 per ton in free gold. They have over 100 tons of the same rock on the dump. Two arastras have been purchased for grinding, there being no mill within the vicinity of Columbia Hill, where it is located. The ledge averages three ft in thickness. Milton Baugh and others are working on a new ledge on the south fork of Humbug creek, about half a mile north of Bloomfield. They have reached a depth of 20 ft. The ledge, which is four ft thick, shows well in sulphurets and galena. Several assays have been made and proved satisfactory. The owners are confident of success.

SIERRA.

DOWNIEVILLE, Jan. 25.—The Bald Mountain gravel company yesterday realized 399 ounces of gold. Average daily yield, about 300 ounces.

TUOLUMNE.

SAN GUISSEPPE MINE.—Sonora *Union-Democrat*, Jan. 24: The San Guisseppe mine is located on Dragoon gulch. Parties who have a lease are taking out ore. The prospects made of rock taken from the pile were rich with gold. The vein is a small one, averaging not more than a foot. The last ore milled paid upwards of $40 to the ton. For some weeks operation was suspended on account of water.

OLSEN.—Ten tons of ore from the Olsen mine have been worked at San Francisco, yielding enough to pay for all work and improvements. This showing proves the great richness of the ore.

LAKE.—Tuolumne *Independent*, Jan. 24: The assays made by Robert Towle from this claim are $900 gold and about $50 silver per ton. An assay made by Mr. Barry, of Quartz Mountain, went $2,300 gold and about $56 silver per ton. The width of the vein is said to be 100 ft, and the ore resembles that of Leadville. Two roads from Sonora have been surveyed—one by Baker's, the other by Crane's flat. Distance from Sonora, 65 miles, with good grade for a railroad.

NEVADA.

WASHOE DISTRICT.

OPHIR.—Gold Hill *News*, Jan. 29: On the 2500 level the main north drift continues in vein matter 140 ft from the incline. In the Hardy vein the explorations north and south, on the 2200 level, are in low-grade quartz.

SIERRA NEVADA.—In crosscut No. 2, 2400 level, running west from the main north drift, six ft of ore has been encountered and the vein penetrated 10 ft. Crosscut No. 3, 205 ft from the incline, is nearing the same ore body. The north drift on this level is in vein material; total length, 225 ft. On the 2300 level the drift north from the east shaft is in 400 ft. Three hundred ft north of the east shaft a crosscut has been started west and run 55 ft, and is in vein matter.

CALIFORNIA.—The north drift from the main crosscut west on the 850 level is 224 ft. The stopes below the 1750 level maintain their yield. The north drift on the 2250 level has its face in vein matter 285 ft from the C & C shaft.

GOULD & CURRY.—A station is being prepared at a point in the joint Best & Belcher cast crosscut, 1700 level, under the new joint shaft, from which to send a diamond drill upwards 540 ft, to tap and drain into the Sutro tunnel the heavy flow of water there encountered. At the O. & C. and B. & B. shaft sinking is going on as usual; total depth of the shaft, 890 ft.

UNION CON.—Good milling ore continues to be found in the drift south and east of the old ore body on the 2400 level, from which the winze is to be sunk to the 2500 level. The heavy vein formation encountered, and which carries stringers of good ore all along, shows signs of making south and down.

MEXICAN.—The north drift on the 2300 level has a total length of 450 ft, leaving 160 ft yet to run to connect with the joint Union winze from the 2000 level, and complete the connections between the Ophir incline and the Union shaft on this level. Connection has been made between the joint Union winze from the 2000 level and the 2300 level by a raise from the Union drift south.

CON. VIRGINIA.—On the 2150 level the joint Best & Belcher crosscut east is in very promising vein matter. Ore is being extracted in No. 1 winze on the 1750 level and east of the old stopes on the 1550 level.

BELCHER.—The east drift, 3000 level, is in 145 ft; south drift on this level, 102 ft. The south drift, 2760 level, is in 30 ft, and the ore vein has been followed on this level over 40 ft.

SAVAGE.—The incline has a depth of 175 ft on the slope below the 2200 station, and is being continued down to meet the drift aimed to connect with it from the 2400 level of the C. N. S. shaft.

UTAH.—The incline has now reached 164 ft on the slope below the 1750 station. The south lateral drift on the 1750 level is in 67 ft from the incline. The crosscut east from the station is in 45 ft.

CHOLLAR.—The pumps have been put to work in double line to the 2400 level. The west drift from the 2400 station of the C. N. S. shaft has a length of 000 ft. From a point 535 ft west of the shaft the drift south for Potosi ground has been started.

JUSTICE.—The raise from the 1650 level has reached the winze from the level above and affords much better ventilation.

YELLOW JACKET.—The shaft has a depth of 2,863 ft. The north winze is now 80 ft on the slope below the 2700 level. The north drift is being extended to meet that from the 2800 level in the Con. Imperial.

ANDES.—The drift west on the 350 level has been turned north, and is following good indications in that direction. The 200 level is being cleaned out and repaired, preparatory to connecting it with the 350 level by a winze.

HALE & NORCROSS.—Strong influx of water hinders progress in the winze from the 2200 level; total depth, 120 ft. The north crosscut, 2200 level, is in 60 ft.

CON. IMPERIAL.—The sump of the south incline has been completed below the 2300 level.

JULIA CON.—The south lateral drift, 2000 level, has some very good looking rock. The winze is down 230 ft and is in porphyry.

ALTA.—Drifting north and south on the 1050 level and in promising vein matter. When these drifts attain a length of 200 ft, each crosscut will be run and the vein explored.

OVERMAN.—The crosscut east on the 1900 level has made good progress.

BULLION.—The sump below the 2350 level of the incline is completed. The station on that level is to be excavated preparatory to crosscutting the ledge at this level.

BEST & BELCHER.—Crosscutting east joint with Con. Virginia on the 2150 level and encountering some promising vein material.

SILVER HILL.—Very promising-looking vein material is still encountered in the face of the east crosscut on the 1300 level.

SUTRO TUNNEL.—The headers of both the north and south lateral branches are in vein material requiring to be timbered.

EUREKA DISTRICT.

EUREKA CON.—Eureka *Leader*: The water problem has solved itself without any work or interference from the management. The flow of water is just as heavy as when it first broke in from the K K ground, but its disappearance is as rapid. It comes in on the twelfth level and pours into a winze sunk to the west of the incline. In the winze it rises within 3 ft of the top, and that is the last seen of it. Oceans of water have been poured into that hole, and still it carries off the immense volume. There is no doubt that an underground channel has been struck, and its opening solves the question of drainage effectually and without cost or expense. The 13th and 14th levels are still filled with water, but they can be

[CONTINUED ON PAGE 76.]

A Review of the Modern Doctrine of Evolution.

CONTINUED FROM PAGE 66.

tbis time is likely to bs wanting from tbe offspring. The causes of accceleration and retardation may next claim attention.

It is well known tbat the decomposition of tbe nutritivs fluids within living animals gives rise, in the appropriate tissues, to exhibitions of diffsrent kinds of forces. Tbese are motion in all classes; heat in some only; in a still smaller number, electricity and light; in all, at certain times, growth-force or hathmism; in many, phrenism, meutal or tbought-force. Tbess are all derived from equivalent amounts of chemical forcs which are liberated by the dissolution of protoplasm. This organic substance, consisting of CHON, undergoss retrograde metamorpbosis, being resolved into the simpler CO_2, HO, etc., and necessarily liberating force in tbe process. None of the functions of animal life can bs maintained without supplies of protoplasm. We bave hsre to do with batbmism. It consists of the movement of material to, and its deposition in, certain definite portions of the growing egg, or fœtus, as the case may be. It is different in its movements in every species, and its direction is probably the resultant of a number of opposing strains. In tbe simplest animals its polar equilibrium is little disturbed, for these creaturss consist of nearly globular masses of cells. As we ascend ths scale a greater and more marked interference becomes apparent; radiated animals display its superior energy in a number of lines over the spacss between them; and in longitudinal animals, a longitudinal axis exceeds all others in extent and importance. In the higbest animals, its results ars much mors evident at one extremity of the axis (head) than at the other, and the diverging lines are rsduced to four (ths limbs). In each species, the movements of this force are uniform and habitual, and it is evident that the habit is so deeply-sated that only a very strong dynamic interfsrence can modify or divert it. What is ths modifying forcs? And how is it introduced?

The characters of living beings are eitber adaptive or non-adaptive; they are either machines especially fitted to meet ths peculiarities of their environment, or they are not. Among the latter may he ranged rudimental structures and also many others of no sufficient use. They ars all dus eitber to excess or defect of growtb force; they are either consequences of a removal of nutritive material to other portions of the hody; or they are dus to an excess of such material which renders an organ or part useless through disproportionate size. Of the former class may be cited the absence of the tail in soms monkeys and birds; also of the teeth in some cetaceans; of the latter kind are tbe enormous tusks of the mammoth, and the recurved superior canines of the babyrussa. The change of destination of this material has been probably due to the construction of adaptive machines whose perfection from time to time has required ths use of larger and largsr proportions of forcs and material.

In considering ths origin of adaptive structures, two alternative propositions are presented to us. Did the occasion for its use follow the appsarance of the structure, or did the need for tbe structure precede its appearance? The following answer to the question has always been the most intelligible to me. Animals and plants are dependeut for existence on their environment. It is an everyday experience that changes in environment occur without any preparation for them on tbe part of living things. If the changes are very great, death is the result. It is evident that the influence of environment is brought to bear on life as it is, or bas besn, and that special adaptations to it on their part must follow, not precede changes of climate, tópography, population, etc. We bave another important consideration to add to this one, viz.; the well-known influencc of use, *i. e.*, motion, on nutrition. Exercise of an organ determines nutritive material to it, and the nervous or other influence wbich does tbis, equally determines nutritive material to localities in the body to wbich an effort to move is directed, whether an executive organ exists thers or not. Tbe habit of effort or use dstermining the nutritive habit must be inherited, and result, in the growing young, in additional structure. Change of structure, denied to tbe adult on account of its fixity, will be realized in the growing or plastic condition of fœtal or iufant life. The two considerations here brought forward lead me to think that the cause of acceleration, in many adaptive structures, is environment alone, or environment-producing movements, wbich in turn modify structure. Tbe character of the stimulus in the successive grades of life may be expressed by the following table, passing from the lowest to the highest:

1. Passive or motionless beings;
   by climate and food only.
2. Movable beings;
   by climate, food and motion.

By motion either;
a, unconscious, or
aa, conscious, wbich is,
b, reflex, or
bb, directed by desire without ratiocination, or
bbb, by desire directed by reason.

The only general rules as to the direct influence of motion on struoture which can be laid down at present are two, viz: That density of tissue is in direct ratio to pressure up to a certain point;* and that excess of growth force in a limited space produces plications of the surfaces stimulated.† These and otber laws, yet unknown, bave probably led the changes expressed by evolution, wbile many otbers bave followed tbe disturbance of equilibrium wbich tbey have produced.

I here allude incidentally to tbe question of transmission or inheritance. It has been maintained above tbat the batbmic force of each species is different from tbat of all otber species. This force is characteristic of some unit of organization of living beings; and tbis probably consists of several molecules. This unit bas been termed by Haeckel the plastidule. The transmission of tbe bathmic force of one generation to another would be effected by the transmission of one or more living plastidules; and tbis is probably precisely wbat is accomplished in reproduction. The *Dynamic Theory* of reproduction I proposed in 1871,‡ and it has been since adopted by Haeckel under tbe name of perigenesis. I compared tbe transmission of bathmic forcs to tbat of tbe phenomenon of fire, which is a force-conversion transmitted from substance to substance by contact. Tbe theory of pangenesis, devised to explain the pbenomenon of reproduction, is to my mind quite inadequate.

III.—Metaphysics of Evolution.

I enter bere upon a wide field, over wbich I can only skim on an occasion like the present. Tbs subject has been already introduced by reference to consciousness as modifying movemsnt. The word consciousness was then, and is now, used in its simplest sense, viz: as synonymous with physical sensibility. Its lowest and most usual exhibition is ths sense of touch; the special senses, taste, sight, etc., ars higher forms, while thoughts and desires ars organized products of the same raw material. Consciousness cannot be denied to many of the inferior animals; indesd, if we grant it to any, we must admit that it is displayed at times hy even ths lowest *Protozoon*. That these humbls creatures should possess it, is apparently quite as probable as tbat the equally simple and very similar bioplasts of the brain of man should be its seat.

Consciousness alone is not a sufficient basis for the development of mind. For this, one more elemsnt is necessary, and that is, *memory*. Impressions made by the environment are registered, and soon cease to be present in consciousness. Under the influence of association the impressions return to consciousness. Associations ars those of place, of the order of tims, and of similarity or differences in various qualities, as size, color or any otber physical features. Experiences of these qualities are to all conscious beings either painful, indifferent or pleasurable. Whsn association requires, events, objects or characteristics, are returned to consciousness in the order in which they cohere most firmly in tbe mind, wbich may or may not bs tbat in which they entered it. The liking for or dislike to the object, are equivalent to an attraction to or repulsion from it. Tbus experiences is begotten: as its material increases new combinations are formed, new relations observed, and in the highest types of mind laws are discovered. No one can deny memory to animals; it is the medium of their education by man, and has been as well tbe means of their education hy nature. It doubtless causes a re-arrangement of certain elements of structure which give the form to consciousness when it arises again. It is also probable tbat thess elements are not the same as tboss which register classifications and conclusions, but that nevertheless the arrangement or organization of these is determined by the simpler arrangements of the perceptive elements. Experiencs produces these combinations in tbe bioplastic aggregations of all animals, be they in the form of ganglia, brains, or less specialized forms. Nowhere in the human organism ars the effects of effort and use so strikingly witnessed as in the increase of brain power; and familiarity with the education of the lower animals shows tbat this is the case with them also, though in a lesser degree.

If, then, we grant the propositions, first, that effort and use modify structure; and second, that effort and use are determined by mind in direct ratio to its development, we are led to the conclusion that evolution is an outgrowth of mind, and that mind is tbe parent of the forms of living nature. This is, however, to reverse a very usual evolutionary hypothesis, viz., that mind is the product and highest development of the universe of matter and force. The contradiction is, however, not so absolute as at first appears. By mind, as the author of tbe organic world, I mean only the two elements, consciousness and memory. But it is the view of some tbinkers that consciousness is a product; that it is not only a correlative of force, but a kind of force. To tbe lattsr tbeory I cannot subscribe; when it becomes possible to metamorphose music into potatoes, mathematics into mountains, and natural history into brown paper, then we can identify consciousness with force. The nature of consciousness is such as to distinguish it from all other tbinkable things, and it must be ranged with matter and force, as tbe third element of the universe.

It is true that unconsciousness does not imply absence of life as generally understood. A majority of the processes of life are performed unconsciously by living creatures; mind itself being no exception to this rule. There is another class of acts whose performance produces sensation, but consciousness is not concerned in tbem as an immediate cause. Therefore, it is a common endeavor to associate reflex and unconscions acts witb the molecular movements of inorganic and non-living substances. But tbs one great difficulty in making this identification bas never been surmounted. Tbis is the different nature of the movements in the two cases. In non-living matter they ars simply polar, notbing more. In living beings they display design. Perhaps I use the word "desiga" in a new sense, but the expression is nevertheless appropriate. What I msan is, that the movements of living things bave direct reference to consciousness, to the satisfaction of pleasures, and to the avoidancs of pains. The *molecular* movements witbin animals of the simplest class are tbe digestion of food and tbe elaboration of tbe matsrials of reproduction. The *molar* movements of the simplest animals are to enable them to escape tbs pains of hunger and celibacy. Moreover tbere is reason why the movements of living bsings display design. We all know the naturc of habits; how tbey are performed unconsciously, and as automatically as digestion itsslf. But did any one ever know of a habit in an animal, wbose origin be could trace, which bas been formed in nnconsciousness? According to our knowledge tbey ars always the result of stimuli which are consciously felt, and which cause hy repstition or by reminiscence a repetition of the resulting movement. After a sufficient number of rspetitions such an act becomes a habit, *i. e.*, is performed automatically, or without the intervention of effort, and frequently without consciousness. It thus becomes a part of the character of the individual or species. Tbis common phenomenon is explained by tbs hypotbesis tbat an organization of the centers controlling action is caused by the efforts of the animal under ths stimulus, and tbat finally a machine is constructed which determines ths nature of the force expended, without further mental exertion of ths individual. Such a process is education, and the result is an acquisition to tbe stock of faculties already on band. Thus is explained the vast numbsr of automatic and unconscious activities displayed by animals; to the same source, I belisvs, the common reflex acts may be traced; it even appsars to me probable that tbe organic functions in general have had ths same origin.* While tbese lattsr have mostly long since passed beyond the control of ths mind, portions of the urogenital functions still linger within ths confines of its jurisdiction. Tbus have consciousness and mind endowed living nature with useful functions; and this, which may be called the *Theory of Endowment*, accounts for ths element of design wbich is so puzzling when seen in unconscious and reflex acts.

As it has been maintained abovs that structurs is tbe effect of tbe control over matter exsrcised by mind, it is evident that the evolution of mind must be directly followed by corresponding development of organism. The science of paleontology substantiates this theory in a wonderful manner. But ths animal mind bsing generally occupied with simple functions, its expressions in structure ars nsually notbing more than the progressive creation of improved instruments for obtaining food, resisting climate, escaping enemies and reproducing tbeir kind. The struggles of animals have been on this platform, and mind has only been necessary to aid in accomplishing the ends above mentioned. Wonderfully effective machines for grinding, cutting, seizing and digging; for running, swimming and flying have been produced. The development of mind proper must appear in the size and structure of the brain; and though the bistory of the latter in past ages must always remain in large part hidden from us, it is known that in tbe former respect tbere has been great progress made in various lines of animals. Now ths line which has carried brain to its present development in man, the *Quadrumana*, has been deficient in special mechanical excellencies of ths kind enumerated above. Perhaps inferiority in these many respects has kept the *Quadrumana* under greater mental tension, and compelled them to exercise deliberation in tbeir acts and give tbat opportunity to thought which was less demanded in tbe case of otber animals. Furtbermore, if they are less specialized in tbeir mechanism than most other *Mammalia*, tbsy are less restricted by it to peculiar modes of life. They are more versatile, and more capable of the adoption of new habits as a consequence. And here we have a glimpse of a most important principle in evolution which is the keynote to its method; tbis is wbat I have called *The Doctrine of the Unspecialized*.

Paleontology shows that tbe succession of living types has not been in a single straight line. It has been in many divergent lines, and a large number of them have not continued to the present time. The history of life has been well compared to a tree with divergent branches, many of which do not reach tbe elevation of tbe summit. Furthermore, in the many cases in which we can trace the lower lines to the present period, it is evident that in their present condition tbey could not have given rise to the higher forms. Each line, in fact, bas developed to an extreme of specialization of structure, which it would seem is incapable of modification in any direction very divergent from tbat which it has already taken. Much less have such specialized types been able to survive the environment for which they were designed: with important changes in that respect they have perished. A few examples will serve to illustrate my meaning. The direction of devsl-opment has been from fishes, through *Batrachia* and reptiles, to birds and mammals. But we cannot derive any living typs from the osseous fishes of the present or past ages *(Hyopomata)*; to find the origin of *Batrachia*, we must pass below tbese to more generalized and older forms, tbe *Dipnoi*, a class whoss position in the system was for years a controverted point. We cannot obtain *Mammalia* from any of the existing types of reptiles, but we must go back to tbe Permian period, and tracs tbeir outlines in tbe *Theromorpha* of that day. In spite of the prophetic resemblance of these remarkable animals, they ars inferior to later reptilia in the structure of their vertebral column, and display resemblance to some of their immature stages, as well as to thoss of tbe *Mammalia*. Among mammals we cannot derive monkeys from *Carnivora* or *Ungulata*, nor ths latter from each other, but can only trace tbeir close approximations in tbe Bunotherian types of tbe lower *Eocene*. So with tbe great divisions of *Ungulata*, *Proboscidians*, *Hyrax*, and tbe even and odd-toed orders must all be traced to tbe unspecialized *Amblypoda*, with small brains and five-toed plantigrade feet, as their ancestors.* It is easy to perceive that the generalization and plasticity of all these forms has furnished tbe ground of their ancestral relation.

We are now in a position to comprehend more clearly the general nature of evolution. Tbe doctrine of the unspecialized teacbes that the psrfection produced by each successive age has not been the source or parent of future perfection. The types wbich have displayed the most specialized mechanism have either passed away, or, undergoing no change, bavs witnessed tbe progress and ultimats supremacy of those who were once their inferiors. This is largely true of animals which havs attained great bulk. Like tbose with perfected weapons, they have ever been superior to tbe attacks of other animals in their day, and doubtless led, so long as food abounded, lives of luxurious indolence. With change or diminution of food, such huge beasts would be ths first to succumb, and it is a fact that no type of animals bas maintained great size through many gcological changes. It is trus that all of the lines of ancestry of tbe sxisting higher mammalia, as the subdivisions of ths *Carnivora*, *Ungulata* and *Quadrumana*, wbich we know in detail, commenced with types of small sizs and insignificant muscular power.

Soms important conclusions may he derived from wbat has preceded. It seems that evolution has witnessed a continual runuing down of types to tbeir great specialization or extinction. That many typss have arisen in weak and small beginnings, but that ths conflict witb mors powerful forms bas developed some qualities in wbich they sooner or later excelled, and wbich formed tbe basis of tbeir future superiority and psrsistence. Tbat while tbis has probably been the true cause of the origin of the many admirable mechanical adaptations displayed by animals, it is pre-eminently trne of the development of mind. That the reason why progress has reached its limit in the lines of greatest specialization, has probably been the removal of the occasion of its original cause—*i. e.*, active exercise in the struggle for existence. This explanation is suggested by the remarkabls degradation which is witnessed in animals whose mode of life relieves them from ths necessity of working for a livelihood, *e. g.*, the parasites, and sessile animals, whose young are free. Some of these creatures, on assuming their parasitic life, lose tbs semblance of even the order to which their young belong. The primary stages of various plants move actively tbrough the water like the lowest forms of animals, and their sessile adult condition must be looked upon as a degeneration. It is well known that the endeavor to relegate ths lowest forms of life to tbe two kingdoms of animal and vegetable bas been generally abandoned. Tbe great vegetable kingdom probably exbibits a life degraded from more animal-like beginnings. Animal irritability and mobility have been lost, and tbeir own consciousness must he entirely eliminated from tbe question of tbe origin of the many later and specialized types of plants. But I venture here the hypothesis that the consciousness of plant-using animals, as insects, bas played a most important part in modifying tbe structure of the organs of fructification in the vegstable kingdom. Certain it is tbat insects have been effective agents in the preservation of certain forms of plants. I would suggest wbether the mntilations and strains they have for long periods inflicted on the flowering organs, may not, as in some similar cases in the animal kingdom, have *originated* peculiarties of structure.

Evolution of living types is then a succession of elevations of platforms on which succeeding ones have built. The bistory of one horizon of life is, that its own completion but prepares tbe way of a bigher one, furnishing the latter with tbe conditions of a still furtber development. Thus the vegetable kingdom died, so to speak, that the animal kingdom might live; having descended from an animal stage to subserve the function of food for animals. The successive types of auimals have first stimulated the development of the most susceptible to the conflict of the struggle for existence, and afterwards fnrnished them with food. Doubtless in the occupation of tbe world's fields, tbe easiest and nearest at hand bave been first occupied, and successively those which were more difficult. The digging animals are generally tboss which first abandoned the open field to more

conrageons or strongor rivals; and they remain to this day generally of low type compared with others of their classes *(e. g., Monotremata, Rodentia, Insectivora)*. All occupations havo been filled before that one which requires the greatest expenditure of energy—*i. e.*, mental activity. But all nther modes of life havs fallen short of this one in giving the supremacy over naturc.

Automatism theu represents a condition of "lapsed intelligence" and diminished lifo. The unconscious automatism of auimals is .a condition of still greater lapse. On tho contrary, sensibility is the coudition of development, and the susceptibility aud impressibility which is the extreme reverso of automatism is the especial character of youth. Here the "doctrine of the unspecialized" finds justification again.

What the futuro hae in store for us in the history of inorganic force and its results we can not nnw forssee, hut I call attention in this connectiou to the important part played by life in tho distribution of minerals. It has long heen known that the carbon of the earth's cruet was once in a living etate, and it ie admitted that tho limestoue once circulated in the flnids of animals. We have recently been compolled to hclieve that siliceous rocks are composed of the consolidated shells of minutc plants, which they have olaborated from the water of tho ocean. Silver and gold are segregated and deposited by seaweeds. The principal rock material whose relation to life has uot been ascertained, is alumina. How far the processes which now charactcrize dead matter wero oncs rslated to life is a problem for the futurs.

IV.—The Morals of Evolution.

The doctrines of the struggle for existence and survival of the fit in human life, have a twofold application. The relative proportions in which these applications are made, will depend on ths moral dovelopmcnt of him who makes thsm. Moral density and ntellectual stupidity (often nearly allied) will see in these two laws ouly the struggle for material power, and the survival of thc strongest. They will hardly urge in these days, as they would infallibly have done hed they lived a few centuries ago, that the strongest means the hardest hitter, or the most successful assassin, but they will probably believe that this pre-eminent position belongs to the most wealthy. From a purely dynamical standpoint this position is correct, yet it might be a useful question for such advocates to consider, why it is that physical oppression and assassination should he less successful avenues to power than they oncs were.

There are two reasons why man does not grant the first place in his esteem to physical force. The first principles of morale are acquired in the struggle for existence. The idea of *meum* and *tuum* was speedily developed so soon as men associated together; and the habit of justice has douhtless heen formed by the insiatence of every man on hie own rights, and hy the power of combinations of mcn to control those who may from euperior strength or other cause seek to violate the rights of property. Thus law originated, and from the earliest history of the race to the present day it has educated the harbarous and semi-harharous to civilization. It is then easy to perceive that man gives the highest place in his affections to the *most just;* hut there is yet another reason why this should he the case.

The reproductive instinct in the lower animals has developed into social affections, and these form a part of the character of the higher animals and, in an especial degree, of man. The eentiments of sympathy and henevolencs are probably outgrowths of the same. While the rational faculties are concerned in the *knowledge* of right, these sentiments are a source of the *love* of right. This dispesition is trusted hy men as leading to the *practice* of right, in casee where the power to enforce it is not immediately present. The struggle for cxistence then among men ranges all the way from a rivalry of physical force, to a rivalry for the possession of human esteem and affection. The rohher and assassin of the lowest human races, are repreeented hy the slanderer and defamer in the higher. The ultimate prosperity of the just, asserted and foretold by prophets and peets, is hut a forecast of the doctrine of the survival of the fittest. The unjust are sooner or later eliminated hy men from their society, either hy death, seclusion or ostracism.

But the organized moral qualities cannot normally transceud in power, as motives of human action, those which secure his physical preservation. Lines of men in whom the sympathetic and generous qualities predominate over the self-preservative mnst inevitahly hecome extinct. Evolution can produce no higher development of the race (whatever may sometimes appear in individuals), than an equivaleucy in these two classes of forces. Beyond thie the organization of the social faculties of the brain must always he repressed in the race, so that we can only expect to attain an equilihrium hetween them and the more purely selfish ones, as the very highest result of unassisted evolution. In this position the judgment is suspended hetween the opposing classes of motives; and it must ever remain douhtful in general, as to whether resulting action will he just and right, or the reverse. I exclude from this qnestion thoee generoue acts which do not appear to the actor to conflict with eelf-interest. These may he termed *sympathetic* acts, and are qnite dietinct from the altruistic. The symnathetic actions are een at timee in most animals. The altruistic acts on the other hand, are thoee that expree what is ueually called "moral principle." Such acts may often ooincide with the interest of the actor, but so long as they do so, they are altruistic. It is part of the doctrins of evolntion, that habits will ultimately disappear nn the removal nf their stimnlating cause. The moral nature originated, and has been maintaiued, through the pressure of the fear of consequences. The removal of this pressuro, through the acquisition of power, will ultimately result in the dimiuution or loss of the moral nature, through dieuse. The abuscs of power ars well knowu. This appears to hs all that evolution cau do for us in the production of the moral naturs. It nnst he admitted that uo organized faculty of *self-sufficient altruistic justice* cau be derived by ths process of mental evolution. It is evideut that any power which shall cause the permauent predominance of the just over the sclfish faculties must he derived from without.

After we omit from customery religion coemogony, which belongs to scieuce, and thcogony, which belongs to tho imagination, we have left an art which has for its object, the developmeut and sustentation of good worke or morals among men. If the teachers and professors of this art produce ths results in this direction at which they aim, their great utility muet be conceded by all. Their method has the advantags over that of the law, in being of the character of inducements supplied before action, iuetead of pains and penalties inflicted after actiou. They strive to *originate* good couduct, rather than to punish bad condnct. They are working on the eide of the *originative* force in development, rather than the destructive; the "*origin of the fittest,*" rathor than the "*survival of the fittest.*" Whether man possessee the spontaneous power called "free will" or not, the work of supplying inducements for good condnct ie most useful to society. But religion, as generally understood, pre-supposes free will; and the definition of the word responsihility implies its existence. The question as to the preasnce of such a faculty is an interesting one, and will now he briefly considered.

Thc well-known doctrine of necessity leaves no place for free will. All acts are the consequnces of motives, and are the outcome of a halancing of interests. The heaviest side of the account determines action. Our physical necessities supply the motives for moet of our activities; our pursuit of food and clothing is of necessity, and no choice is free from it. Evolution supports and explains this doctrine, as can readily he perceived. It derives our intincts from an ancestry whose daily occnpation hae been their gratification. But it has been shown above that this development does not supply the motives of an independent morality.*

The direction of action under stimnlus is determined hy intelligence, which is, as has heen above maintained, the product of experience. Intelligence is organized or classified knowledge, and directs the activities set on foot by the likes and dielikes, that is, the affections. When there is knowledge there is no necessity for epontaneons action or free will, since action is determined hy the organization of the mind. If the mind is conscious of insufficient knowledge, an inducement to seek knowledge ie eupplied, and according to the result of investigation will he the direction of knowledge.

But we are here brought to face the case where knowledge cannot he, or is not, obtained. Thie is the condition of the two questions of the practice of morals and the nature of the future life. The evolution of mind consists of a continual advance from the known into the unknown, and a transfer of the unknown to the known, and so long as there is any inducement to progress of this kind, and nature responds to inquiry, development will go on. Although it is true that it ie only among men, and hut few men at that, that the pursuit of knowledge is an occupation, most men add to their etock incidentally as they pursue other avocations. The knowledge of right and the inducements to its practice are learned in their every-day intercourse, eo far as it can he acquired. But it is in this field that knowledge soon attains its limit, and accordingly development dependent on knowledge must cease. If any further progress is to he made some new force must intervene at this point.

Here is the opportunity for the appearance of will or spontaneity; here it is at least needed. I am willing to helieve that it appeare at this point, and that so long as we have to face the unknown in moral progress, so long it will remain. Probahly if organized as a faculty it may always continue, even after much of the unknown may have heen conquered, and a etationary period may have ensued. Such an accession to character would he a fitting crown of evolution, and a justification of this lahor of the ages. If a true factor in human development, it might he compared in the creation of character, to the apical of a growing tree. As the part pre-eminently living, it leads the growth of the trunk aud hranches. They all follow of necessity the path it has marked out. Under its lead they are successively formed, become fixed, and finally decay.

* On the Origin of the Will. *Penn. Monthly*, 1877.

It is estimated that not loss than 28,000,000 tons of anthracite coal will he required to supply the demands of the market in 1880. To produce this immense quantity will keep the mines husy during the entire year, requiring a production of more than a half a million tons a week.

Useful Information.

How to Judge of Leather in Belts.

Without entering into the question of the merits or demerits of rubber or other kinds of helting, one cannot hut uotice the want of unanimity of opinion, even amoug belt manufacturers, as to what really constitutes the hest leather for making belts to convey power iu running machinery; and, if we includo makers of belts on the other side of the Atlantic, the differencee in theory and the divergence in practice are much wider than they aro hero. As a rule, too, this is a matter about which machinists generally have hnt little information, and are, with here and there only a raro exception, hut indifferent judges.

The hest helt, theoretically, is that which combines tho highest tensile strength with the greatest power to resist wear by attrition, heing at the eame time subject to little change hy dryness, moisture, heat or cold. These qualities, supposing the manufacture to he ordinary good, are mainly dependent npon the tanning. In Europe there is very little difference known or acknowledged between good sole and good belting leather. The heaviest or "plumpest" leather is usually considered there the hest for helts, as well as for the solee of hoots and shoes. Our belt makers, however, recognize an essential difference. The sole of a hoot or shoe, particularly in all heavy work, needs to have but little flexihility, hut must have the greatest possihle capacity to resist wear by attrition, and he ae far as practicahle, impervious to water, while it is never enhjected to any test of ite tensile strength.

Sole leather, therefore, in all the toughest wearing grades ie made as thick and solid as the tanner can make it; great care is taken to open wide the peres of the hide, in the early part of the tanning process, see that all the gelatine is saved to combine with tannin, and that the hide is left in the tan liquors long enough to take up all the tannin it will absorh. This makes the finished leather oftentimes a great deal thicker than the original hide. But such leather, it need hardly be said, would not he the hest for making helts, for it has little flexihility, and its tensile strength has heen greatly impaired hy thc straining of the fihers of the hide to take in the large amount of tannin it has received.

The tanner who would make the hest belt-leather, however, although he cannot swell the fihere of the hide with tannin to the extent ahovs noted, must produce a firm, solid helt with not a little of the elasticity and strength of steel; it must he sufficiently flexihle, and yet of great power to resist wear hy attrition, and to stand, with little etretching, the heaviest direct strain. These qualitiee are best ohtained by an amount of tanning which will make the finished leather hut little thicker than the raw hide of which it is made. On cutting a piece of sole or helting leather, one will notice the network of hide fibers interlacing each other, and which, before tanning, were surrounded with gelatine. These fihers give the hide its great tensile strength, and any considerable displacement of them hy the transformation of the hide into leather impairs this quality. A piece of good helt leather, therefore, when freshly cut, should look hright, with the intervening spaces hetween the fihers fine, even and regular. The texture shonld he nniform throughout, and with the utmost eolidity there should he great elasticity.

Peculiarities of Rapid Motion.—If a musket hall he fired into the water it will not only rehound, hut be flattened; if fired through a paue of glass, it will make a hole the size of the hall without cracking the glass; if the glass he suspended hy a thread it will make no difference, and the thread will not even vibrate. When a tallow candle is loaded in a musket and fired at a hoard of not too hard a wood, it will make a hole in the heard. If a round disk of naper is turned very rapidly on a lathe, its edge will cut the fingers like a knife; and if such a disk of sheet iron is turned with eufficient velocity, it will even cut steel.

Testing Cellars for Dampness.—Provide yourself with a thermometer, a glass tumhler filled with water; and a piece of ice; then notice how low your thermometer, when placed in the tumhler, has to sink before any moisture hegins to show itself on the outside of thc vessel of cold water. The lower the temperature to which the thermometer has to sink before moisture is precipitated, the less there is of it in the moisture of the cellar.

New Kinds of Plated Sheet Iron.—In Iserlohn, Westphalia, thin sheet iron ie plated with alloys of nickel, or cobalt and manganese. A half of one per cent. of mangancse makes cohalt and nickel very malleahle, fluid when melted, and ductile. The plates, which are already in the market, are heautifully white and brilliant.

To Remove Old Paint.—Slake three ponnds of stone quicklime in water, and add one pound American pearlash, making the whole into the consistence of paint. Lay over the old work with a brueh, and let it remain for from 12 to 14 houre, when the paint is eaeily scraped off.

To Remove Ink Stains.—Wash carefully with pure water, and apply oxalic acid; and, if the latter changes the dye to a red tinge, restore ite color by ammonia,

Good Health.

Cause of Drunkenness.—Dr. Jackson expresses the opinion that one of the mest common inducements to ths uso of alcohol, is that people overwork themselves, and heiug eo exhausted that they cannot sleep, resort to smoking, chewing and alcohol drinking. This may somctimes be the case, but we can testify to having learned hy observation that men do not become drinkers hecause they cannot rest, but because instead of devotiug their leisure hours to useful reading and proper entertainments, they epend them in driuking ealoons among dissipated companions, or they drink at home to kill time. When a mau is fatigued from hodily labor, all ho has to do is to keep his mind occupied with reading, or have others read to him, and he will soon feel eleepy. Ths kind of reading has, of couree, much influence, and a man must learn hy experieuce what kind of literature will keep him awake, and the sort that will cause him to sleep.

Table Salt an Aperient.—Phyeicians have for a long time known that common tahls salt is an efficient aperient in ordinary cases of constipation. In a lecture on a casc of nervous affection, Dr. Weir Mitchell, of Philadelphia, said that he had recommended the patient to take sach morning on rising a tumhlerful of water—cold, to prevent nauseating—in which was dissolved a teaspoonful of tahle salt. "This simple aperient," the doctor adds, "I frequently employ in cases of constipation, and generally find it efficient. There is great advantage in etarting the howels and in kceping them in a soluhle condition, particularly in cases of nervous dieordcr in women, as it eometimes clears up obscure poiuts in the casc, and at all events eliminates ono sourcc of error."

How People Get Sick.—Eating teo much and too fast; swallowing imperfectly masticated food; using too much fluid at meals; drinking poisonous whisky and other intoxicating drinks; repeatedly using poison as medicines; keeping late hours at night and slecping late in the morning; wearing clothing too tight; wearing thin shoes; neglecting to wash the hedy sufficiently to keep the pores open; exchanging the warm clothes worn in a warm room during the day for costumes and exposure incident to evening parties; compressing the stomach to gratify a vain and foelish passion for dress; kceping up constant excitement; fretting the mind with herrowed troubles; swallowing quack nostrume for every imaginary ill; taking meals at irregular intervals, etc.

The Medicine of Sunshine.—The world wants more sunshine in its dieposition, in its business, in its charities, in its theology. For ten thousand of the aches and pains, and irritations of men and women we recommend snnshine. It eoothes hetter than morphine. It stimulates hetter than champagne. It is the hest plaster for a wound. The good Samaritan poured out into the fallen traveler's gash more of this than of oil. Florence Nightingale used it on the Crimean hattlefields. Take it into all the alleys, on hoard all the ships, hy all the sick heds. Not a vial full, not a cup full, but a soul full. It is good for spleeu, for liver cemplaint, for neuralgia, for rheumatism, for failing fortunes, for melancholy.

Nervous Failure.—When men do not die of some direct accident of disease they die, in nine cases out of ten, from nervous failure. And this is the peculiarity of nervous failure—that it may he fatal from one poiut of the nervous organism, the rest heing sound. A man may, therefore, wear himself out by one mental exercisc too exclusively followed, while he may live through many exercises extended over far greater intervals of time and involving more real lahor if they be distrihuted over many seats of mental activity.

Onions as a Medicine.—A correspondent of an English agricultural journal says that onions are a poison for worms, and that a dish of hoiled onions given to a child suffering from worms will kill them. Another correspondent maintains that they are the best remedy for rheumatism, eithcr cooked or raw, while a certain medical man says that hoiled onions are good for a eold in the chest. We are glad to hear all this, and hope it may he true and verified hy further experiments so that onione will at least be good as medicine if not for food.

Sanitary Errors.—It is a popular error to think that the more a man eats the fatter and stronger he will hecome. To helieve that the more hours children study the faster they learn. To conclude that if exercise is good, the more violent the more good is done. To imagine that whatever remedy causes one to feel immediately hetter is good for the system, without regard to the ulterior effects.

Disinfectant for the Breath, etc.—A very weak solution of permanganate of potash is an excellent disinfectant for light purposes, euch as rinsing spittoons, neutralizing the taint of diseased roote of teeth, cleansing the feet, and keeping the hreath from the odor of tohacco smoke. Permanganate is not poisonous.

A Simple Chest-Protector.—A folded newspaper placed over the cheet ineide the vest, on going out during cold weather, constitutee an excellent protector for the lunge.

Dividend Notice—Black Bear Quartz Mining Company.
Stanford Ore Feeder, Joshua Hendy, S. F.
Chemicals and Chemical Apparatus, Bullock & Crenshaw.

The Week.

Another cold wave is sweeping over the country, and as is usual with very low temperatures, it has a depressing influence upon business and industrial circles, which will be but temporary.

There is a general advance in prices of merchandise, wares and metals, which indicates the approach of more prosperous times and a revival of financial and business confidence.

The directors of the Central Pacific railroad have made heavy sales of their stock, and the public impression is that they contemplate withdrawing from it by future sales of the balance of the stock in their hands.

There is an increasing interest manifested in mining properties both on this coast and in the Eastern cities. Attention in the latter circles appears to be attracted at present to Colorado, New Mexico and Arizona, and large investments are being made in the mines located there. New and valuable discoveries of gold ledges in our own State have been made, which will add to its already high character as a gold producer. The rich output of the mines at large, combined with the practical application of business economy and management in their development and working, are convincing capitalists that this field for investment is really the most desirable one that is open for future efforts.

DR. GEORGE LITTLE, the State Geologist, says that a yield of $10,000,000 worth of bullion might be produced in Georgia every year without exhausting the ore within this or the next generation.

THE bottom fell out of a lead mine in Iowa a short time ago. Two men named Foster and Morgan had just left the working when it sunk into a subterranean lake.

THE work of laying steel rails in place of iron ones on the California Pacific from Davisville to Suisun has begun.

THE German government proposes to levy a tax on advertisements in newspapers.

A Proposed State Mineralogist.

The Committee on Mines and Mining Interests of the Assembly has transmitted letters to Henry G. Hanks, William Ashburner, Melville Atwood and Hamilton Smith, soliciting their responses by letter to the following questions: First—Do you think that the establishment by law of an office, to be known as the State Mineralogist, would tend to the advancement of the mining interests of California to a sufficient degree to justify the cost of the maintenance? Second—If yes, will you please favor the committee with your views in relation to what by law should be made the scope of such an office, and somewhat in detail the duties of its incumbent? Third—What steps should be taken by the Legislature to secure the early preparation of such a report as that referred? Should this office be created simply until a report could be made, or should it be permanent, with a yearly report? The gentlemen are requested to transmit any other suggestions which occur to them.

We have also to suggest that others in the mining community, who have given this subject thought, should express their views as well. We should be glad to receive from any practical miners their opinions on the subject, and will publish such letters and afterwards see that they are brought to the attention of the members of the Committee on Mines and Mining.

If such an office were created, and the incumbent a good, practical men having the interests of his task at heart, no doubt much benefit would result. If some mere politician, with no special fitness, were appointed, the office would be of no use at all to the people. There are questions coming up every day which the State Mineralogist would be called upon to determine, and he should be a thoroughly competent man, who would try and make the results of his labors of some value to the mining community.

The Wiegand Amalgam Refining Process.

In our issue of Dec. 20th we printed a paper of great value to the producers of base bullion from the pen of our townsman, E. N. Riotte, setting forth the results and rationale of a very simple process for refining base bullion while it is yet in the form of amalgam, the costs of which, *exclusive of power and steam for heating*, appear to be a shade short of two per cent., while the saving of discount on sale of bars is four to five per cent.

Elicited thereby, to-day we print a communication from Conrad Wiegand, Esq., now the leading public assayer at Virginia City, Nevada, in former years well known in this city as the superintendent of assaying at our U. S. Mint.

We commend it to the perusal of practical millmen, whether their amalgam is produced base or fine, but especially to those whose amalgam contains but a small amount of gold, so small as often to be ignored in assaying, because the costs of parting (separating) it from silver exceed its value, whereas, under the new system it does not.

It is evident that at no distant day, when Mr. Wiegand's Edison-like patience—patience alike with people and with perplexities—shall have fully perfected results, which in the gross and outline he has already silently achieved, it is evident that his exceedingly simple process is destined to supersede acid refining and parting upon several grades of silver, which have hitherto called for dissolving the whole silver, *and with it base metals also*, in acid, so as to allow the insoluble gold to settle to the bottom of the dissolving pots, whence it is collected, washed "sweet" from acid, melted, minted or sold.

It is equally evident that the Wiegand method must soon affect the price of bluestone favorably to those who can obtain from him a license to use his process; while at the same time the increased use of bluestone (sulphate of copper) for refining lead-base amalgam, as well as for "basing" the amalgam yield of slimes and tailings must increase its price to the general consumer.

We feel a more than ordinary interest in the success of this process, for the simple reason that the MINING AND SCIENTIFIC PRESS Patent Agency, has conducted his numerous patent cases for years. How comprehensive and inevadible the claims are which have been granted, largely due it is true to his own critical ability in handling the English language, our readers can infer from a circular recently issued, which we reprint less as a characteristic than as a model document. It is designed to warn foundry-men, millmen and others against an apparently contemplated infringement. This circular reads as follows:

VIRGINIA AGENCY OF THE NEVADA AMALGAM REFINING CO., December 1, 1879.

To George M. Jennings, Esq.:—Your attention is hereby specifically called to the following facts:

1. The Nevada Amalgam Refining Co. is incorporated under the laws of California, and has an agency at Virginia City, Nevada.

2. Said company is now the owner of certain patent rights, which secure to it and to its licensees the exclusive right, *by means of any possible machinery, apparatus or implements*, to do the following things:

First—To refine silver, and separate it more or less completely from other metals than lead, by leaching its mercurially diluted amalgam out of (or away from) the amalgams of other metals, using mercury (warm or hot) as a filtering solvent, followed by a cooling of the filtrate and collecting therefrom the precipitated (or newformed) silver amalgam, whether by straining or by crystallization upon cooling surfaces, or upon obstructions fixed in channels through which the filtrate is made to flow. See patent 145,265, December 2, 1873, and re-issued June 23, 1874.

NOTE.—Mercurially to leach away the amalgam of lead (or of any other metal more soluble in mercury than silver is) from silver amalgam is not in contravention of this secured right, simply because leaching metals of the lead-base class away from silver, is the direct *opposite* of leaching silver away from metals of the copper-base class; and being far more obvious and facile of execution, has often been crudely empirically and imperfectly used, though never developed to an innocuous and systematic method; but the possibility of first dissolving a sufficient percentage of silver amalgam in mercury and then quickly effecting its precipitation, without at the same time *proportionately* effecting the solution and precipitation of amalgams of the copper-base class (making it possible to found a new system of refining thereon), was undiscovered till 1865 or 1866; and then only as the result of close study, toilsome experimente and considerable outlays. It was patented 1873.

Second—This company (and its licensees) also possesses or controls the exclusive right to feed in quicksilver *(for the purpose above set forth)* at the *top* of any vertically set vessel containing mixed amalgams, which vessel *while its sides are impervious to quicksilver* is furnished with a strainer at the bottom, thereby gravitatively securing the passage of quicksilver throughout the amalgam. Patent 145,265, re-issued as above.

Of course, if such a vessel were set so that its sides would be horizontal (one "side," viewed *gravitatively*, then being at the "top" and the other at the "bottom," while the strainer would then form one "side"), and if the quicksilver-feed were applied to the other end (or mid-way between two ends, each end having a strainer affixed), it would be a mere *verbal* evasion of this second recited right, and as such would be enjoined by the courts, as any other mere evasion would be.

However much superior to a vertical flow a lateral flow might prove (secured centrifugally or otherwise), so long as the sides of the vessel, *viewed with reference to the current of quicksilver passing through it*, are substantially impervious to quicksilver, while the current enters one end and strains or filters through the other (or, entering medially, strains at both ends or at a periphery) that method of using quicksilver in the United States *for the purpose set forth* requires a license from the Nevada Amalgam Refining Company to escape an injunction on the use of any such apparatus *for that purpose*, and to avoid a prosecution even if used, counterfeiter-like, secretly when the facts can be proven.

Third—This company and its licensees also have the exclusive right to maintain a leaching circulation (constant or intermittent) of the *same* quicksilver through heated amalgams for refining purposes, by means of which, without waste and without being itself consumed, a comparatively small amount of quicksilver, by successive increments, may refine a large amount of copper-base amalgam. Patent 145,265, re-issued as above.

Fourth—This company also possesses the exclusive right to a *gold*-refining process, which consists essentially of a *combination* of the silver-separating process above recited, with other steps which by themselves are not patentable, but the whole, constituting a new method, are; as is fully set forth by patent No. 168,695, October 11, 1875.

Fifth—This company and its licensees also possess the exclusive right to separate amalgams of *differing specific gravity* by causing their comminuted and disintegrated suspension in a vertically descending *current* of quicksilver, with or without the use of a top or bottom strainer; which current is so speeded as to overcome the slight gravitative tendency of silver-amalgam to float in quicksilver, but *not* sufficiently speeded to overcome the stronger tendency of heated copper-amalgam to float in quiescent quicksilver. See patent 196,848, Nov. 6, 1877.

Sixth—This company and its licensees also possess the exclusive right to *force* leaching quicksilver hot through amalgams, *in any direction whatsoever*, which amalgams have *not* been diluted (or "thinned up") by quicksilver, and whether by hydrostatic pressure, steam pressure, air pressure, by a pump, or by any other method of forcing such a flow. See patent No. 219,152, Sept. 2, 1879.

Seventh—This company and its licensees also possess the exclusive right to *construct, sell or use* for mercurially refining leaching purposes any leaching box or digester which embraces the following features:

A cavity in a box or vessel (of any desired form) enclosed between suitably supported straining cloths, into which cavity base amalgam is to be put for the purpose of refining it by mercurial leaching. Nor can any owner of *lead*-base amalgam lawfully use such a digester without first obtaining our license. See patent 219,152, Sept. 2, 1879.

3. The exceeding simplicity and economy of our methods and of our appliances for refining base amalgams, producing as they do silver free from gold, and *exempt from all mint* charges*, creates a powerful tendency with men either morally obtuse or reckless to imitate and seek to evade the company's rights; and although the terms on which they are offered to the producers of coppery amalgam are so low and exceedingly favorable, there is evidence going to show that an attempt to evade the company's rights is in serious contemplation.

In view of these facts, by authority of the President and Board of Trustees, I hereby notify you—

First—That any foundry or machine-shop whose managers shall knowingly construct or sell or use such a leaching box or digester as above described without license from this company will be dealt with according to the law for such cases made and provided.

Second—Any party who shall *buy* such a machine, unless licensed by this company to *use* the same, will be restrained by due process of law from using it, and will be sued for all provable damages and expenses of every kind arising out of the attempt; and, furthermore, HE WILL BE DENIED THE USE OF ANY OF OUR PROCESSES ON ANY TERMS WHATEVER, and in all PLACES whatsoever; so that while any honorable millman will be able by the cheap use of our processes to effect important savings in the sale of his bullion and be able to pay good prices for milling materiel, the attempting infringer will not be able to compete with him. This rule has been adopted in order to identify the interests of licensees with those of the company, AND WILL BE RIGIDLY ADHERED TO.

Third—As soon as it is possible for the subscriber to secure capital for the erection of bluestone works, such *payments* for copper will be made to the producers of coppery amalgam as will render the base metals which now enhance *discounts* on base bars a source of *profit* to their owners.

Alike, therefore, for right, for honor, for manliness and for self-interest, it is hoped that every producer of base amalgam, no less than every man of right impulses who detests piracy, will frown down in its incipiency the attempt to evade patents which have cost so much to a struggling man in the development of an overlooked principle into a useful process, promising so much of good to so many, and offered on terms so reasonable that it is difficult to conceive of thanklessness so cold as not to *want* to requite (by *self-helpful* business) a man who has strivenearnestly for the interests of silver producers, now that he has achieved a working success in an invention which he knows entitles him to the respect and good-will not only of bullion producers, but of all others whose business success depends on the continued running of mills in the production of bullion from the *wastes* of our mines. CONRAD WIEGAND.
Superintendant Nevada Amalgam Refining Company.

To the above we intended to add a communication just received from the inventor, whom we hope to see rise into the American peerage of the rich, for no one among all our friends seems more worthy, especially as such an elevation could not be declared the result of either the patronizing favor of the already wealthy, nor the luck of stocks. If attained at all it will be the unqualified result of the persistent use of a clear head, a hopeful heart, an indomitable will, all backed by a peculiar and almost amusing energy and wit, tireless as the tide themselves.

The crowded state of our columns compels us, at the last moment, to postpone publication of Mr. Wiegand's letter until next week. It will, however, "keep," and will speak for itself in our next number.

* Because it saves the Government the costs of purchasing copper to alloy coins.

SUCCESS OF THE BEAR RIVER UNDERCURRENTS.—Some months ago, Wm. H. Kinder, an enterprising miner, of Gold Run, Placer county, commenced the construction of an undercurrent on Bear river, several miles above Colfax, in which to collect the gold that ran to waste in the debris that flowed into that stream from the hydraulic mines adjacent thereto. This was the first construction of the kind on Bear river, although similar undercurrents have been used in other localities with success. We learn that Mr. Kinder's experiment has yielded unexpectedly large returns—the first result, after an 18 days' trial, being $600 in gold. At the time the work on the undercurrent was commenced its estimated cost was $5,000. Upon this cost the above return shows that the venture will be an exceedingly profitable one, yielding over $18,000 per annum.

VULTURE MILL.—Mr. Shipman has been appointed Superintendent of the Vulture gold mine and mill. Only 20 stamps are now running on Vulture ore. The mill is now known as the Central Arizona Co. mill. The Vulture mine will soon have an 80 or 100-stamp mill erected at the mine, to which water will be taken in 11 miles of six-inch iron pipe.

New Mining Enterprise in Siskiyou Co.

Siskiyou is an old mining county, and in many parts of it, particularly about Yreka, rich diggings have been worked. The country in that vicinity, however, is very flat, affording few opportunities for dumps, so the mining has been confined, to a great extent, to work with rockers, etc. Only the shallow deposits of top gravel have, therefore, been worked, and this class of work is going on to this day. All the patches of top gravel which were accessible have been mined, but the lack of fall has prevented any extensive hydraulic mining, as the lower gravel could not be got at.

Some years ago, this section was examined by capitalists, who proposed running a tunnel to cost some $100,000, but after spending several thousand dollars in a thorough investigation, they found that the tunnel, if made, would not open up enough ground to make it a paying investment; so that the enterprise was abandoned. A ditch, some 80 miles long, now furnishes water to the mines which are being worked.

The ground in the vicinity of Yreka creek has paid well as far as it has been worked, but no deep mining has been done there for this reason stated. A company has recently been formed in this city, however, under the style of the Yreka Creek Gold mining company, with 50,000 shares capital stock, to work the deeper part of the ground, intending to overcome the difficulty of lack of fall, by using the Cranston hydraulic elevator. The incorporators have investigated the merits of the machine, and in view of its success where introduced, are confident that the rich ground of the deep diggings of Yreka creek can be utilized.

They have purchased the big ditch, which has for many years brought in water for working the rich side creeks and slopes of Yreka creek, and have secured several miles of good ground, thus owning both water and ground. They are going to work in earnest, having set aside 15,000 shares of their stock as working capital, at $1.50 per share.

The upper ground has all paid well. A large amount of money no doubt remains, as the lower dirt has not been touched, nor could it without some such device as the Cranston elevator. Of course it would not pay to put up expensive pumping works to work gravel mines. The ground is about a mile and a half below Yreka, down the creek.

We saw this week at Joshua Hendy's shop, No. 51 Fremont street, which is the office of the company, the patterns of the large elevator which is to be used on this ground. It is a 20-inch machine, the largest yet made and is capable of taking what ground 700 inches of water will sluice down. Some of the water is brought back after lifting the gravel and used for washing it. With the pressure of water they have they expect to be able to work ground 35 or 40 feet deep.

We illustrated and described the Cranston elevator in our columns some little time since. It is set at any suitable point in the claim, below the surface, and by delivering a sufficient stream of water into it from above, the water and gravel are driven up hill by hydraulic force. An inclosed flume is made with an inclination upward, with a horizontal ground section made of cast iron. A hydraulic nozzle is introduced into this ground section, the nozzle being pointed in the direction the water is to go. This ground section has an open end back of behind the nozzle, where the water and gravel or material enters the machine. The open end is connected with the flume, placed in the bottom of the mine and the gravel is washed or driven into this flume in the ordinary way. At the opposite end of this ground section is connected the upward inclined closed flume, and also connected at its upper end with the flume to the top of the mine so as to discharge the material and water elevated into the flume on top. This machine is driven by the nozzle which discharges inside of the ground section.

It will be evident from the above, that if there is sufficient force exerted by the water discharged from the nozzle of the machine to drive it, that earth, sand, gravel, and rocks entering the machine must necessarily be carried along, and be discharged with the water into the flume on top. The water, gravel and material are made to travel through the machine at high speed by the direct action of the force exerted by the nozzle of the machine. All of the gravel and material comes in direct contact with the stream of water discharged from this nozzle, consequently it serves greatly to dissolve and pulverize all gravel that is hard and difficult to work. In this connection it may be stated there is no possibility of the gravel choking or lodging in the machine. The thing never occurs while the machine is working under pressure. The disintegration and washing process above alluded to, produced by the force of the nozzle of the machine, so thoroughly washes and dissolves the gravel in its upward passage through the elevator spout, that expensive long flumes for washing are not necessary, the gravel being washed better in a single passage through this machine than in traveling one mile through an ordinary flume. The machine is in use in a number of places in this State.

The Gould Process at Meadow Lake.

A short time since we gave a brief account of the results of a new process, introduced by Mr. Gould at Meadow Lake, a locality where the ores have been heretofore found impossible to work. Meadow Lake has been called the "bone yard of processes," so many having been tried there and failed. We received this week the following letter from a gentleman who gives us more of the details of the process than have before been published, and which shows some startling results. The statement is a plain and open one and will repay perusal:

EDITORS PRESS:—I have noticed articles in the PRESS several times concerning the working of the ores of Meadow Lake district, all of them being of such a nature as to cause a person unacquainted with the ore and our method of working it to doubt our ability to do what we claim and have done. Being deeply interested in the welfare of the district, and knowing your influence will do a great deal toward reviving interest in it, I make a statement of our work at Carlisle which is about seven miles from Meadow Lake and where the same kind of ore is found, Meadow Lake district embracing both which is a mistake. We had our ore assayed by Prof. Thomas Price, of your city, and after giving him the number of tons worked, he said he never knew of ore being worked to a higher percentage, we having worked it to nearly 95% of the assay value, realizing from a run of 13 tons $1,176.63.

The tailings assayed 2.07 in gold and 3.49 in silver per ton. The ore came from the U. S. Grant mine, and was worked in an 8-stamp mill having two pans and one settler. The engine has power enough to run but one-half the machinery at once, and having started late in the season, we could not run over one-third of the time on account of scarcity of water, and yet after paying all expenses of building a furnace, packing wood and provisions, we were enabled to declare a fair dividend after crushing 20 tons.

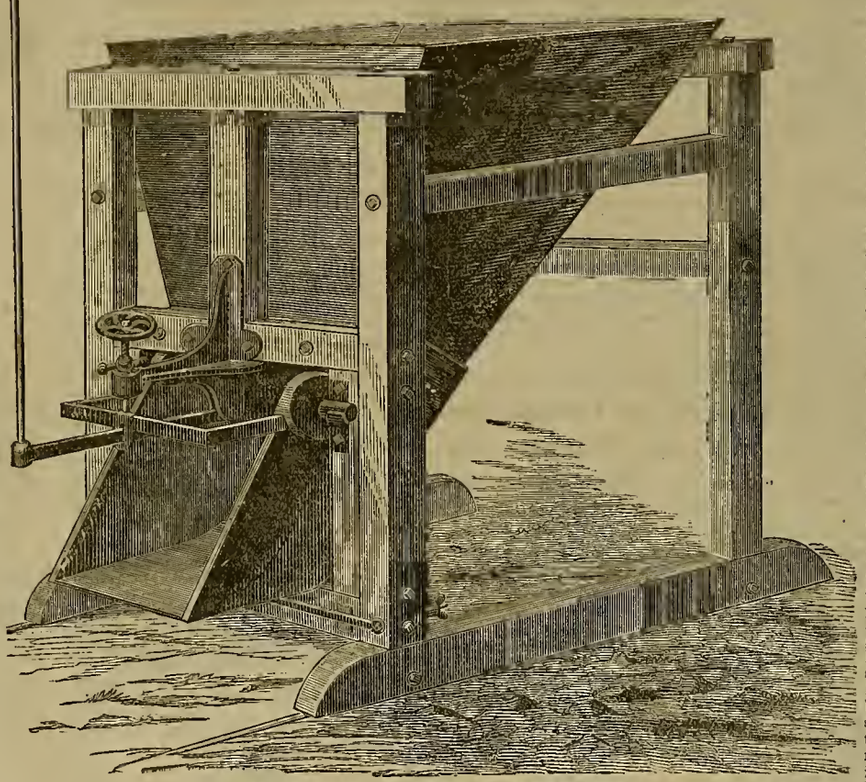
The loss in quicksilver was so small as to be not worth considering. At present we are not doing anything on account of the snow, but as soon as we can get provisions in, which will probably be in April or May, we will commence running, and we extend a cordial invitation to any who may wish to do so to visit us and satisfy themselves that we do what we claim.

All that is necessary to make Meadow Lake one of the best bullion-producing districts on the coast, is to have moneyed men interest themselves, build mills of sufficient capacity to handle at least 20 tons per day and develop the mines. The ore can be worked for $5 per ton provided 20 tons or more can be worked per day, which can be easily done with proper works; and, considering the fact that there is plenty of ore worth from $20 up into the hundreds per ton, very handsome results could be realized.

We have worked ore from all parts of the district and have not asked or received a particle of help from any one. Knowing the reputation the district has we are willing to give every one the benefit of our work, feeling satisfied it is the only way to bring it before the public.

This statement may not satisfy many doubters, but to such I will say, if you wish to satisfy yourselves by visiting us, drop me a postal card expressing such a desire and I will cheerfully let you know what time we will commence operations in the spring. JAS. B. GIFFEN.

Truckee, Jan. 26, 1880.



THE IMPROVED STANFORD ORE FEEDER.

The Stanford Ore Feeder.

The engraving presented herewith represents the improved Stanford Ore Feeder, manufactured by Joshua Hendy, 49 and 51 Fremont street. Since Mr. Hendy began to manufacture this feeder he has made many changes in details of construction which have greatly improved it. The essential feature of the carrier or feed table, moving in the arc of a circle, is, however, preserved. This carrier is supported on side journals on the frame, and is swung back by the tappet of the stamp stem operating the rod and lever, the ore falling into the battery as the stamps require it. As the pressure is relieved by the lift of the stamps, the carrier comes forward against the regulator ready for the next stroke. The best ore feeder is that which keeps the smallest amount of ore under the stamp, and does not allow iron and iron to come together. The stamps will then do the largest amount of work. By the use of a good ore feeder there is 20% more ore crushed than by hand feeding, and 15% less wear of iron.

The regulating screw shown in the engraving, regulates the amount of throw by striking against the bail, at the point where the lever passes through, the amount of feed being thus regulated. This machine for dry crushing is equally as good and durable as the "Challenge Ore Feeder," also manufactured by Mr. Hendy. It is now sold at the low price of $75—the cheapest ore feeder in the market.

The Hofmann Process.

A short time since we gave from the pen of Mr. Guido Kustel, a description of a newly patented process of Mr. Ottokar Hofmann, for treating auriferous silver ores. Mr. Aaron and Mr. Dostkan, both expressed surprise at a patent being granted for what they considered old processes, used successively. Mr. Kustel in our last issue answered their objections, which has called forth from these gentlemen the following rather shrap replies:

EDITORS PRESS:—In your last issue I find in answer to my remarks on the alleged novelty of the Hofmann process, Mr. Kustel's defence of its claims.

He begins by assuming that there is a vast difference between an argentiferous gold ore and an auriferous silver ore without any points of contact between both; furthermore, accuses me of claiming the introduction of the Patera method before Plattner in 1865, while in fact I simply claim the introduction of salt roasting in connection with the Plattner in that year at Grass Valley, not for the purpose of chlorinating the silver contained in the gold ores treated, but to prevent the excessive consumption of chlorine in the subsequent impregnation by the alkaline earths, chiefly magnesia, an improvement of great value in the chlorine process in general. He continues by doubting that simplicity is an important element in a practical process, and finally, to cap the climax, expresses by insinuation his doubt of my ability to make experiments anyhow, reserving very modestly this heavenly gift to himself and Mr. Hofmann exclusively. Mr. Kustel triumphantly claims a success for his process.

But let us look at the facts of the case. Mr. Hofmann treats his gold-bearing silver ore with the Kiss process to extract the gold and silver at the same time. He finds his tailings too rich in gold and treats them by the Plattner; his result is 95% of the gold and silver.

He has found a good way of treating his ore, but has he found a new process? Mr. Kustel says his process is a combination of the Kiss—not Patera—and Plattner processes. He says the Kiss process extracts both silver and gold and the Patera does not. I say both processes extract gold, the hyposulphite of soda as well as lime, and I substitute the Patera for the Kiss in his combination. Does he still consider it his patent? Will he answer this question? For my own part, as I mentioned before, my results on tailings treated previously for silver by the Patera and subsequently by the Plattner were entirely unsatisfactory, and the future will show the practical use of the alleged novelty of the Hofmann process to be limited. Mr. Kustel tells us that the hyposulphite of lime had to be completely leached out to get a good result by the Hofmann novelty. Will he explain why this should be so, when it is easily decomposed by the chlorine used in excess in the subsequent Plattner. In my experiments on tailings my results were poor, no matter how completely I freed the residues from hyposulphite.

Mr. Kustel further on *pretends* to believe that I claimed a patent on the chlorine process, while he *knows* that my patent covers but a system of apparatus in connection with the process, which he amongst the rest of chlorinators adopted in this State.

Finally, Mr. Kustel remarks that any metallurgist leaving from $12 to $18 per ton in the sulphuret tailings hardly understood his business, a statement not surprising to me in view of his limited experience in this metallurgical branch of our profession; $18 per ton in roasted ore represents but $13 per ton of raw ore, as all highly concentrated sulphurets lose not less than 20% to 30% in weight by roasting and leaching. As the original ore carries perhaps $130 per ton in gold, it represents but a residue of 10% in the tailings, and is not a poor result by any means on many troublesome sulphurets in this State.

In conclusion, Messrs. Editors, permit me to express my surprise at the want of consideration and gratitude manifested by Mr. Kustel, considering the fact that to *me exclusively* is he indebted for all his earlier knowledge of the Cali-

CONTINUED ON PAGE 76.

The Engineer.

The State Engineer and the Debris Question.

The report of the State Engineer was handed to the Governor last week, and is now in the hands of the State Printer. It is understood that the following positions are taken with reference to the drainage of the Sacramento valley and the mining debris deposits:

First—The valley rivers, already much deficient in capacity to carry the waters of ordinary floods, are annually in the most important divisions, becoming less capable of performing this duty.

Second—The great primary cause of this deterioration of the channels, is the flow of sands from the canyons into which the mining detritus is dumped.

Third—The carrying capacity of the streams and their efficiency as drains have been greatly injured, and the problems of regulating the drainage of the valley has been much complicated by the injudicious location of embankments, and ths uneven results of leveling along the rivers.

Fourth—The river channels never were capable of passing the waters of ordinary floods through some of their divisions, without material rectification thereof, and the attempts to confine flood water by the simple construction of levees without systemization, and the aid of other devices to improve the channels themselves, could not have succeeded generally, even though the sand flow had not come down the rivers.

Fifth—The very existence of Steamboat slough, an important branch of this river, as a navigable and flood-carrying channel, is threatened—as evidenced by its rapid filling within recent years.

Sixth—In the natural order of things, we may look for the serious impairment of the navigable qualities of the lower portion of the main river in the near future.

Seventh—The presence of this sand in the upper rivers, whence it is liable to be brought down in great quantities, impairs the confidence which ought to exist in the success of whatever plans may be projected to regulate and facilitate the drainage of the valley, and hence it is doubly important to ward off the danger.

Eighth—If the deposit of detritus in the streams were to cease at once, yet would it be necessary to restrain in the canyons that which is already there, and regulate the flow of the sands therefrom, in order that we may count with any considerable degree of certainty upon the efficiency and permanence of drainage works in the valley.

Ninth—This danger can be warded off, in a great degree at least, without radical interference with existing interests.

Tenth—The restraint of the sands in the canyons admits of no delay. It is the first objective point in the restoration and improvement of the carrying capacity of the valley streams.

Eleventh—If this desirable result were measurably secured, the natural action of the rivers—relieved from the load they now have to carry—would be to excavate their bede and gradually work back to the regimen of 20 years ago.

Twelfth—The accomplishment of this result can be greatly hastened by engineering devices and works, and subsequent management thereof, and under any plan this treatment of the natural drains must form the chief feature of the scheme for providing rapid passage for the waters.

Thirteenth—As it would have been eminently practicable to have improved the carrying capacity of the streams to a very great extent before they became injured by the sand-flow, so as they are brought back to their former regimen, may their rectification and enlargement of capacity be carried far beyond that point.

Fourteenth—This filling of the main channels, though confined to the Feather river and the Sacramento below the Feather, does—by raising the flood lines at the junction of the rivers—reduce the slope and capacity of the Sacramento above the point of junction, causing greater overflow and seriously complicating the problem of drainage in the upper valley.

Fifteenth—The inter-dependence of works for the prevention of overflow throughout the valley has been so completely demonstrated by the mishaps and disasters of the past, the solution of the problem of drainage here presented can only be hoped for when the work is carried forward with the one object of disposing of the waters as a whole, and not, as heretofore, for purposes of the reclamation of separate parcels or districts of land, and, therefore, it is essential that these operations should be under one head.

Sixteenth—The direct injury to valley lands, caused by the flow of sand and "slickens" over certain large tracks thereof, does not represent the measure of harm thus far done to the agricultural interest; for other lands are in danger of similar submersion, still others have been rendered less fit for cultivation by having the flood lines raised in the adjacent streams so as to make them swampy in character, and the great body of the low valley lands has become less valuable because more difficult of permanent reclamation by reason of the injury to the flood-carrying capacity of the rivers.

Seventeenth—On the other hand, however, there are lands in large bodies which, as they stand now, are more valuable than before the stream beds were raised. For having been dry lands of poor soil, they have been rendered moist and tillable in a high degree by the raising of the sub-surface waters in them, which has followed as a consequence of the raising of the streams.

Eighteenth—Without doubt much of the mining detritus can be kept out of the main canyons, thus largely diminishing the quantity to be there reservoired, but how far this remedy, or prevention rather, may be applied, can only be determined by special examination of the various properties.

Nineteenth—This is a subject of great scope and importance, directly affecting the welfare and prosperity of a large portion of the people of the State, and the problems involved are of the gravest character, so that their solution cannot be arrived at, or fully marked out even, in a year.

Twentieth—Remedial works can only be carried out by degrees, and the detail of treatment which the subject must receive can only be determined upon finally, as the partial results attained point out the way, and by such policy a satisfactory issue may be looked forward to with hope and confidence.

[NOTE.—These last conclusions will be illustrated in the report on Mining Detritus.]

The study of this matter having brought me to a sense of the absolute necessity for organized effort in these matters, I can only recommend that the State take charge of the drainage ways and all drainage works, and exercise such control over them as will regulate their use, promote their improvement, and systematize the construction and management of all works designed to promote rapid drainage and prevent inundation.

As to who is to pay for the necessary work, it does not appear that any suggestions find a proper place in this report. I may remark, however, that nothing which has been said is to be interpreted as meaning that I see no way of accomplishing the desired end except by State work. On the contrary, while some of the works necessary are certainly such as the State might, with propriety, contribute towards, the great bulk of the work is such as should be paid for by the property in the drainage districts whose waters are to be purified and conducted away. And it would seem strange in view of the immense amount of property affected, if the necessary funds could not be secured by organized effort.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1879.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, $7.50

The Explorers', Miners' and Metallurgists' Companion.

Comprising a Practical Exposition of the Various Departments of Exploration, Mining, Engineering, Assaying, and Metallurgy,

Containing 672 Pages and 83 Engravings

BY J. S. PHILLIPS, M. E.,

Of California, a Practical Operator for Thirty-eight Years; Explorer, and Resident in the Pacific States and Territories for the past Twelve Years.

PRICE—bound in cloth, $10.50; in leather, $12.

For sale at this office.

— ALSO —

The Explorers' and Assayers' Companion,

(Third edition.) Price of Vol. I, $6.

Forwarded (post-paid) from the MINING AND SCIENTIFIC PRESS Office, by DEWEY & CO.

HOW TO STOP THIS PAPER.—It is not a difficult task to stop this paper. Notify the publishers by letter. If it comes beyond the time desired you can depend upon it we do not know that the subscriber wants it stopped. So be sure and send us notice by *letter*.

Fine Engraving.

The Engraving Bureau belonging to the office of this journal is prepared to design and engrave all kinds of WOOD CUTS for illustrating newspapers, books, catalogues, cards, circulars, advertisements, labels, badges, seals, etc., in the best style of the art. Our portraits and illustrations of machinery, buildings and landscapes, are superior. Good engravings can be made from paintings, lithographs, steel and copper plate prints, photographs, models, patent office or other drawings. We have a photographic department and the best of machinery for producing accurate and perfect work at the lowest prices. Original maps, charts, and diagrams are made by our NEW PHOTO-RELIEF PROCESS at greatly reduced rates. By the same process copies can be cheaply and quickly produced of printed cuts, in *fac simile*, or they can be enlarged or reduced with equal facility.

Any hand writing in perfectly black ink on clear white paper for manuscript letters or circulars, will be accurately reproduced in metal plates suitable for common printing. Also, *fac simile* signatures, monograms, sheet music, etc. We excel in trade cuts and matched plates for combination color printing. With a large business, long established, and every facility for improvement, we can guarantee more than ordinary satisfaction to all of our patrons. All interested are invited to send for or call and see specimens and obtain prices.

Orders for electrotypes, stereotypes, steel and copper plates, lithographing, stamps and seal presses executed at low rates.

MINE BROKERS,
No. 324 Pine St., room 7,
SAN FRANCISCO, CALIFORNIA.

Mining properties examined, surveyed and reported on; Ores and Minerals Assayed or Analyzed; Sales Negotiated or Capital procured for development.

Connections in London, Paris, Berlin, Vienna, New York, Boston, Philadelphia, Baltimore, St. Louis and Chicago.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claims from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco

To Railroad Men, Mining Superintendents, Street Railroads and Lumber Dealers!

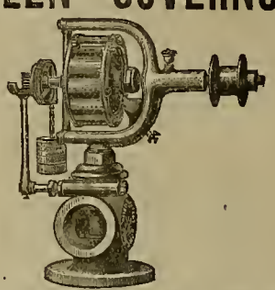
Wheels of every Size and Description
From A. Whitney & Sons, Philadelphia.

WILLIAMS, DIMOND & CO.,
218 California Street, San Francisco

ALLEN GOVERNOR.



This Governor is now being generally adopted throughout the United States and Europe. It is without doubt the

Most Perfect Engine Regulator in Use,

And will in most cases save its cost several times a year. It is invaluable on a QUARTZ, FLOUR or SAW MILL ENGINE, or in any Manufacturing Establishment, where Regularity of Speed is desirable. By being able to run the engine to its full capacity, these Governors have in many cases added

Ten Per Cent. to the Productive Capacity of a Mill,

Thus saving more than their cost every week in the month. Every Engine to which this Governor is attached will run with the throttle wide open. The speed of the Engine can be changed by a simple adjustment of the weights. It will give a UNIFORM SPEED WITHOUT REFERENCE TO THE BOILER PRESSURE. It is simple in construction and not liable to get out of order.

Every Governor warranted to give perfect satisfaction. Thirty days given for a trial, and if it does not fulfill all that is promised, it can be returned at our expense.

In ordering, state the kind of engine, diameter of cylinder, stroke, speed, and average pressure.

Send for full descriptive circular.

RANKIN, BRAYTON & CO.,
Sole Agents for the Pacific Coast,
No. 127 First Street, San Francisco, Cal.

DISSOLUTION OF COPARTNERSHIP.

The partnership heretofore existing between George Spaulding and Solon H. Williams, in the city and county of San Francisco, under the firm name of Spaulding & Williams, is this day dissolved by mutual consent.

George Spaulding alone is authorized to collect the outstandings and accounts, and will pay all claims against the late firm.

GEORGE SPAULDING,
SOLON H. WILLIAMS.

Dated at San Francisco this 1st day of November, 1879.

The business of job printing and publishing in all its branches will be continued as heretofore by George Spaulding, at 414 Clay St.

Ingersoll Rock Drills.

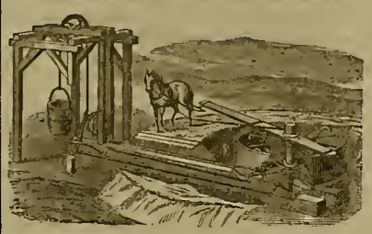
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.
The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing.

REYNOLDS & RIX, 18 and 20 Fremont Street, San Francisco.

DEWEY & CO.'S
Scientific Press Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other Agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (postpaid) 50 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

CONTINUED FROM PAGE 69.

cleared and kept free whenever the company decides to pump them out.

COMO DISTRICT.

AN IMPORTANT ENTERPRISE.—Reno *Gazette*: The Iron Mountain Co. has a very large body of magnetic and hematite iron ore lying 3¼ miles from Clipper Gap station, on the Central Pacific railroad. The company was incorporated in 1864 by G. W. Applegate, B. F. Myers, A. C. Neale, John R. Brown and Chas. Robinson, with a stock of half a million. The entire property of the company was recently purchased by J. E. Judson, the Giant powder man, Scott, the San Francisco foundryman, and Hotaling, the liquor merchant. Surveyors have been at work for some weeks running lines for wagon and railroade out to the track, looking up timber lands, etc. Works will be put up at once for making pig iron. An expenditure of $270,000 will be necessary before work can be begun. The furnaces selected will use 3,000 bushels of charcoal per day.

ARIZONA.

MORNING STAR.—Papago *Citizen*, Jan. 17: This mine has two shafts 10 and 15 ft deep, with a five-ft vein of solid metal of high grade to average fully $150. Specimens go over $400, and there is every indication of a large depoeit.

BUCK.—The Buck is an old working with an 80-ft shaft and fine walls. The vein is about two and one-half ft wide, and averages $132. Full $200,000 worth of ore is in sight, if the indications hold out.

SILVER BELL.—This mine has a shaft 25 ft deep, with a 20-inch vein of ore running $144.

CONSTITUTION.—This is an old mine, with one shaft 92 ft deep and another 54 ft; has a considerable number of slopes.

SILVER NUGGET.—A drift ie being run north on the 45 level. The ore now being taken out will carry from $2.50 to $3 per pound.

IRENE.—The shaft is down 100 ft, all in ore. As it goes down the galena disappears and the ore is a gray carbonate of a richer quality.

SILVER ERA.—A fine quality of ore is still being obtained from this mine. Specimens indicate very high-grade ore.

EAST RICHMOND.—They are striking large bodies of rich ore.

TUCSON ITEMS.—Conaiderable work is being done on mine located a few miles from Tucson. Mr. B. Salazar ie opening up his Black Metal claim. Mr. J. D. Andrewe is doing assessment work for Col Sykes, on the Buena Vista mine, and has started a tunnel which is to tap the vein at a depth of 200 ft. The slight developments already made show some good ore. The Silver Moon mining company have several men at work on some of their property, with fair ore and good prospects. Messrs. Labaree and Davis are also doing some work in the Evergreen district, with encouraging prospects. Developments on the Hope mine, by Mr. Samuel Hughes, show high-grade ore and a large, well-defined vein. These mines are within a distance of 10 to 20 miles from Tucson.

COLORADO.

TROPIC.—Georgetown *Courier*, Jan. 15: The bottom of the working shaft ie in ore that aesays between $500 and $600 per ton.

FREELAND.—The Freeland is producing 75 tons of ore per day, and the product will be increased to 120 tons. The cost of concentration is 75 cents per ton. The ore in sight is estimated at nearly $2,000,000.

BASSICK.—Silver Cliff *Prospector*, Jan. 13: As the work of excavating goes on richer and more inexhauetible bede of ore are revealed. Over $2,000 worth of ore is daily brought to the eampling works of Silver Cliff, and crushed and made ready for shipment to Omaha, where it is reduced and refined. The Bassick is a wonder, and speake loudly for the mineral riches of this section. That our geme may sparkle it ie only nceeeeary to tear off their rude covering.

EL DORADO.—Denver *Tribune*, Jan. 14: At a depth of 25 ft mineral was struck, running 250 ounces eilver per ton. Thus eucouraged the owners stuck to it, though snowed in and alone (their fellow proepectors on the mountain having sought a more congenial clime), until a few days ago, when one of them came out on snow-shoes, bringing with him samples of ore which assayed over 4,000 ounces silver per ton. These were taken out at a depth of 40 ft.

BONANZA.—They are taking out ore running from 250 to 500 ounce in silver per ton.

COLORADO DIAMOND TUNNEL.—*Miner*, Jan. 10: The tunnel ie completed a distance of 1,503 ft, and ie one of the best in the county. No. 4 lode hae been developed by drifting and raising about 250 ft, from which some very rich ore has been taken. The west shaft of No. 5 returns from $70 to $630 per ton. On what is known as the Engine level of No. 5 lode, ore has been taken out giving from 50 to 700 ounces per ton. Ore from the 130 level runs from 50 to 453 ounces per ton.

CORRY CITY.—The shaft ie 120 ft deep, and a tunnel intersects the lode about 60 ft deep. At that depth a mammoth true fiseure vein carries ecattered ore throughout, an average eample of which gave 30 ounce eilver per ton.

M. B. HYNDMAN.—*Register-Call*, Jan. 16: Shaft 40 ft deep. The ore yields from threeaud a half to eight ounces gold per ton.

CYCLOPS.—The lowest grade ore sold to the Boston & Colorado Smelting Co. brought over $180 per ton and the highest over $400.

BLUE BIRD.—The last returns from the emelters gave 50 ouuces silver per ton. The Valley works from the same material gave 142 ounces.

MONTANA.

MOOSE.—Butte *Miner*, Jan. 13: It lies southeast of the Magna Charta. The diecovery ehaft is down 40 ft on a narrow streak of ore which has widened to a three-ft ledge of very fair ore. About 400 ft southeast of discovery a ehaft is 45 ft in the ledge, which is wide. The ore assays 63 ounces in silver and $4 in gold. About 100 ft east a shaft ie down 55 ft.

ALICE.—The breast of ore on the 400 level is looking magnificently; still continuing to hold its great width, and they are now extracting from it eome wonderfully rich ore, a great deal of which looke ae though it had been literally plastered over with silver. On the 500 level the west drift is looking finely, and the present indications are that it will prove richer than the 400 level.

MOUNTAIN.—The rich chute of copper ore dips to the east. Ledge is 8 ft wide, carrying ore, of high grade in copper and rich in silver. At the main shaft the bottom shows the richest and largest body of ore yet discovered in thie section of the country. They are raising from 10 to 15 tons of first-class copper ore daily, besides which a large quantity of second-class ore is extracted. It lies upon the dump awaiting the completion of the new smelter.

CONDOR.—The main ehaft ie down 150 ft. The ore body on the 63 level is very large and etrong, being at one point 23 ft wide.

BLACK BEAR.—Siuking has been resumed on the main shaft. They have come into a very promising-looking body of ore about two ft in width. The etope east on the 50 level is still yielding considerable high-grade ore, and the face of the drift shows about two and one-half ft of ledge matter, some of which ie very rich.

SELF RELIER.—The main shaft ie down 63 ft. In the ledge no walls have been found. The widtb of the ledge is therefore undecided. A drift has been run east 40 ft on the 50 level. The drift is seven ft wide and all in ore, a great deal of which assays high. One assay went 60 ounces in silver and 75% manganese. East of the main shaft another shaft has been started, and ie now down 24 ft. The bottom shows a 10-ft lode of low-grade ore carrying a heavy percentage of manganese.

GAONON.—The etopes on the upper level, from which the free-milling ore is extracted, have widened out and materially improved in character. The large and exceedingly rich body of base ore, which ie at preeent being opened on the west drift of the 150 level, is also looking remarkably well. The ore in places on this drift is fabulously rich. They are extracting from 12 to 20 tons of free ore daily.

GRAY ROCK.—They are drifting east and west on the promising ore body encountered in the croecut. South from the main ehaft it ehows from three to four ft wide and assays quite high. A great deal of bass ore is also being developed ou this mine, eome of it of an exceedingly high grade.

FISHER.—The main shaft is down 25 ft, following this ledge, which varies in width from one to four ft; the ore assays 50 ounces. The ledge in the bottom ie somewhat broken. They are now sinking another ebaft east of the main shaft. The ledge at thie point ie etronger and better defined than in the old ehaft; tbe ore also assays somewhat higher.

LEXINGTON.—Large quantities of ore are being daily extracted, most of it coming from ths stopes east of the main ehaft where, in spite of the enormously large quantity of ore already extracted, there seems to be no difficulty in taking out sufficient to keep Davis' mill running full blast. The ore body in this mine, although not very wide, is fully 800 ft in length, and all pay. Stoping hae been principally confined to the workings east of the main shaft. The various drifts run west from that point have been driven with a view of ascertaining as nearly as possible ths pay chute. The ore body developed has proven so large that it hae been deemed unnecessary to carry on the prospecting below water level, it being estimated that there is now in eight sufficient ore to run Davis' mill for three months.

MORNING STAR.—Shaft No. 2 is being sunk as rapidly as possible, and has now attained a depth of 60 ft, still following a two-ft ledge of very rich ore. They are making preparatione to erect a whim on this ehaft, the water having become very troublesome and the old whim on the old ehaft being unable alone to successfully cope with it. Sinking ou the west shaft has been for the preeent euspended, and will not be resumed for some time. The stope west of shaft No. 2 begins to look finely, and is yielding a large quantity of very high-grade ore.

NEW MEXICO.

MINING ITEM.—*Grant County Herald*, Jan. 10: We learn that Malcolm McGregor is working upon a copper lead, recently discovered, about seven miles south of Georgetown and three miles west of the Mimbres river. The discovery was made some six months since, and Mr. McGregor commenced operations about a month ago. The ore is principally carbonate and red oxide with some native copper intermingled. It is about 45% copper. The lead is well defined, is between seven and eight ft wide on the surface, and this width increases as greater depth is reached. The ehaft is now nearly 30 ft deep, and it is Mr. McGregor's intention to push on to the depth of 50 ft, and should the mine hold out, as it now promises, work will be continued on it throughout the entire winter.

LONE MOUNTAIN DISTRICT.—Of the mines now being worked in the Lone Mountain district, five are regarded as taking the lead. Of these the Campbell No. 1 shows a breast of ore about 30 ft in width, and running under the mountain, with a dip of about 25 degrees. Work has been pushed on this incline to a depth of some 30 ft, and every foot of development has shown improving quality of ore. That which is now being taken out mills from 100 to 300 ounces to the ton. The mine ie regarded as the finest thing in the camp. The Home Ticket and Two Jacks, owned by Froet and Palmer, also ehow splendid ore in large quantities. A batch of three tone taken from these mines, and recently worked by T. W. Holson, in the Lone Mountain mill, returned over 500 ounces to the ton.

News in Brief.

KEARNEY is en route to California.

PARNELL arrived at Cleveland, O., Saturday.

The Hofmann Process.

[CONTINUED FROM PAGE 73.]

fornia practice of the chlorine process. Or doss he deny that I gave him the privilege to take his notes on my practice of the process at my works ou the San Bruno road, San Francisco, in 1863, for his publication on "Silver and Gold Extraction." Or again does he deny that he begged the privilege, which I generously granted to him, of a few days' observations and study of my practice at my works in Grass Valley in 1865 or 1866, for the purpose of incorporating it in his second publication? Does he deny that he promised to give me full credit therefor, and how did he fulfill his promise? On this subject in some other number. G. F. DEETKEN.

San Francisco, Jan. 26, 1880.

Mr. Aeron explains his connection with the Patchsn process, and disclaims any pretention to the inventing the use of copper di-chloride in amalgamation, as follows:

EDITORS PRESS:—It is not desirable to occupy your columns with squahbling, yet I must ask leave to say a few words in answer to Mr. Kustel's defense (?) of the Hofmann patent.

I never claimed the use of copper dichlorids in amalgamation, as anyone who reeds my hook may see.

The Patchen process, to my connection with which Mr. Kustel perhaps alludes, consists in ths use of the copper chlorides in a peculiar manner, with peculiar apparatus, in connection with iron pens.

The Hofmann processs is not a *combination*, but a *succession* of known processes, pure and simple. They are coupled, like cars in a train, not combined.

The Kiss process is simply a modification of the Patera, in which, for cheapness and convenience, the salts of calcium are substituted for the similar salts of sodium.

The Patsra *does* extract gold as well as the Kiss. I have extracted by it at ths rats of $84 psr ton, mors than 50% of the gold contained in the ore.

Mr. Kustsl thinks that an operator who leavss $18 per ton in his tailings does not understand his business. I have a pile of sulphuret tailings of Mr. Kustel's own makiug. I have sampled that pils. It assays gold $17.58, silver $10.52, or a total of $28.10 per ton.

C. H. AARON.

The Boiler Inspector Act.

Meetings of the Judiciary Committes of ths Board of Supervisors were held last week to give dealers and workers in iron an opportunity to enter a remonstrance ageinst ths appointment of a Boiler Inspector, which had been recommsnded by the Board of Fire Commissioners. Mr. F. A. Gibbs said that he had for four years resisted the appointment of a Boiler Inspector, and had been sustained in his resistance by all the iron dealers, foundrymen and nearly all boiler owners of the city. Hs rsviewed the legislation on this subject, and pronounced the act of the Legislature as a schems concocted by blackmailers. Mr. Gibbs spoke at length, citing facts and circumstances to sustain the assertion that the appointment of an inspector would he contrary to public policy, and would elicit the oppoeition of all reputeble deelers in iron. When the bill providing for the appointment of an Inspector was presented to the Legislature of 1875-6, Representatives from all counties except this asked that their counties be exempt from the operations of the proposed law. He seid he looked upon the law ae a blackmailing one, which would work great hardship on owners of boilers, as it would require them to have boilere constructed of iron costing 50% more than that now in use.

Irving M. Scott, of the firm of Prescott, Scott & Co., said that there would be no objection to a Boiler Inspector on proper conditions, hut under the present law the position was capahle of being used as an instrument of oppression and extortion. Not only were all boilers for engines to be exemined every year, but even the steam tanks in private kitchens had to undergo a similar examination at an expense of $3 per year. Then it was possible for the inspector to rule that only a certain kind of fixtures and material, which could be bought only of one dealer, should be used, eo that he might get a commission on the sales, and the whole thing turned into a blackmeil machine. The speaker further said: I think the origin of the law was to make a place for some one. It has been said that it was done in the interest of some iron firm, but I don't think there is anything in that. No inspector is required, as the owner of the property is the most effective inspector. There is a difference between an explosion and a hursting. The theory of explosions has never yet heen explained, hut a bursting is giving way of a weak epot in the hoiler. He said also that more explosions hed occurred in Pittsburg, where inspectors are employed, than in San Francisco.

Ira P. Rankin of the Pacific Iron Works said: There has never heen a popular call for this lew. The tax-payers must be on their guard against schemes of this kind, for I consider it a scheme. It will oppress manufacturers. Whoever fills the place will have much power for evil. He can recommend certain firms to the detriment of othsrs, and in a fictitious ssnss will he an expsrt, and can abuse his influence and power to injure the mechenics of ths city. It is a rich vein for the movsrs of the law, and they fully apprsciate the value of it. All manufacturers of boilers are ageinst the law, and I do not think any puhlic interest will hs suhserved by it.

J. V. Hall, of the Sacramento Boilsr Works, said: This qusstion is not agitated for the appointment of an Inspector of Boilers particularly, hut for the power and influence attached to the position. I have never hsfore heard of such an arbitrary movemsnt as this proposition. When a men is given the power to say how a boiler shall he made, his power then becomes dangerous. It should bs done as it is in other countries. Have an inspector who examines a hoiler and then reports to a Board of Commissioners.

Supsrvisor Litchfisld—If I undsrstand Mr. Scott's theory, it bshooves every man to look afsr his own boilers.

Supervisor Taylor—Are not most of the accidents caused hy neglsct or carelessness?

Mr. Hall—In nearly evsry instance this is the cause. Nsw hoilers are more apt to explode than old ones.

Mr. Wheelsr, of the firm of McAfee, Whseler & Co., said, with a new boilsr there is no necssity of an inspector, as the enginser engagsd should bs a sufficient judge of the condition of the boilsr. If this appointment should be necessary, the inspection should be mads by insurance companies, as is dons in Europs. There inspectors examins the boilers before they are insured.

Mr. Moynihan, of Moynihan & Atkin, said: This bill calls for a tsst of a hoiler every six months. Now, every time you test a hoilsr the weaker you make it. If this Boiler Inspector tssts a hoiler and weakens it so that it bursts, who then is responsible? Ws have no accidents here because we are responsible for our own actions, but the moment you get a Boilsr Inspector, we are not responsible. Thers is Spreckels & Co., who have from 18 to 20 boilers, and they are held responsible; but if one of their boilers is inspsctsd and tssted to-day, and should burst to-morrow, and kill 100 persons, no damage could be rscovered from the firm, as they would have the inspector's csrtificate. I have known of but one boiler explosion in this city in 23 years.

Mr. Dickey, of the Risdon Iron Works said: This law, if enforcsd, will utterly condemn all the hoilers in San Francisco. Soms time ago we refused to build a boilsr the thickness rsquired by the United States law, because we considered it would he unsafe to run. This law will hamper the progress of boiler manufacture, if not ceuse complets stagnation. I do not think any hoilers in the city could conform to ths law.

L. B. Benchley of the Pacific Rolling Mills hsld that engineers wers responsible, and the appointment of an inspector would rsmove the responsibility from the proper parties, who were the owners of the property and the employers of the engineers.

The Judiciary Committee afsr the mestings at which the above statements were made, presented at the meeting of the Board of Supervisors on Monday evening, a majority report in the metter of appointng a Steam Boiler Inspector, on recommendation of ths Fire Commissionsrs. The Committee rsports unanimously against any action beiag taken on ths recommendation of the Board of Fire Commissioners under the act of the Legislature.

"The suhject of imposing additional conditions," eay the Committee in the report, "in the granting of privileges to erect steam boilers and tanks, or in the examination of those in operation, your Committee recommend a reference to the Committee on Fire Department, for if additional conditions should be deemed necessary, your Honorahle Board possesses ample power to impose them."

The Committee recommended the adoption of the following resolution:

Resolved, That the San Francisco Delegation in the Legislature be, and they are hereby, required to use their best efforts to secure the passage of the bill entitled "An act to repeal an act approved Merch 27, 1876, eutitled 'An act for the appointment of Inspector of Stationary Steam Boilers, and for the better security of property in the city and county of San Francisco.'"

This report as well as the resolution was adopted.

The eubject hae etill further heen discussed by the members of the San Francisco delegation at Sacramento, but no definite action has yet heen taken on it.

It ie hardly probahle that the statements made by the practical men above mentioned, can be entirely ignored by the Legislature; nor does it seem likely that they will persist in any course which will cause the appointment of a Boiler Inspector, when the men who are conversant with the subject etate that it will do more harm than good.

THE Panama eteamers will hereafter sail on the 5th and 20th of each month, with the exception of the City of Panama, which will leeve on February 4th. The eteamers which leave on the 5th will touch at Mazatlan, Manzanillo, Acapulco, San Jose de Guatemala and La Libertad, taking freight via. Acapnlco for all Central American ports. The steamere of the 20th will touch at Acapulco, San Jose de Guatemala, La Libertad and Puntas Aronas.

OUR AGENTS.

Our Friends can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. Tharp—San Francisco.
R. W. Crowell—California.
A. C. Knox—Pacific Coast.
G. W. McGrew.—Santa Clara county.
J. B. Bachelder.—Shasta County, Cal.
James Rogers—Oregon and Washington Ter.
Thos. H. Manning—Nevada, Idaho and Montana Ter.
Capt. W. H. Seamens—Arizona.
M. P. Owen—Santa Cruz County.
H. E. Hallett—Los Angeles County.
Perley P. Kilbourne—Sacramento County.
M. B. Starr—Contra Costa county.
F. M. Vaaden—Alameda Co., Cal.
C. A. McMahon—Butte Co., Cal.
W. B. Turner—California.
J. W. A. Wright—Merced, Tulare, Kern and Fresno counties.

Every new subscriber who does not receive the paper, and every old subscriber not credited on the label, within two weeks after paying for this paper, should write personally to the publishers without delay, to secure proper credit. This is necessary to protect ourselves and subscribers against the acts and mistakes of others.

Bound Volumes of the Press.—We have a few sets of the back files of the Mining and Scientific Press which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce, and valuable for future reference and library use.

Fresh attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

Sample Copies.—Occasionally we send copies of this paper to persons who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

Extra Copies can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Atlanta Mining Company.—Location of

principal place of business, San Francisco, California. Location of works, West Tintic Mining District, Juan County, Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the Second day of January, 1880, an assessment (No. 1) of Five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, No. 420 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Fifth (5th) day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Friday, the Twenty-Fourth (24th) day of February, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

A. F. McGrew, Secretary.

Office—Room 7, No 420 Montgomery street, San Francisco, California.

Butte Hydraulic Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 2) two levied on the Thirty-first day of October, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't
E Peirson	13	2½	$25 00
L Laplerre	22	2½	25 00
H Marcoux	24	2½	25 00
J B Lussier	25	2½	25 00
John Britt	26	2½	25 00
Geo W Deitzler	37	5	50 00
N Desautelle	41	2½	25 00
Jos Lucier	42	2½	25 00
N Goldtree	43	7½	75 00
Geo Moreau	44	5	50 00
Z Gervais	45	10	100 00
Geo Moreau	46	5	50 00
Geo W Deitzler	47	15	150 00
A S Hawes	17	10	100 00
J Callandreau	4	10	100 00
A M Wilder, Trustee	1	10	100 00
A L Lengfeld	5	5	50 00
L L Dennery	6	5	50 00
W E Lutz	7	5	50 00
Geo. H. Powers	11	5	50 00

And in accordance with law and an order of the Board of Directors made on the 31st day of October, 1879, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the company, room 3, No. 220 Sansome street, San Francisco California, on Monday, the 22nd day of December, 1879 at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

L. L DENNERY, Secretary.

Office, room 3, No. 220 Sansome St., San Francisco, Cal.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock of the Butte Hydraulic Mining Company is postponed to the Fifth day of January, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock is postponed to the second day of February, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

San Francisco, Cal., January 3d, 1870.

Gila Silver Mining Company.—Location

of principal place of business, San Francisco, California. Location of works, Reveille Mining District, Nye County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of January, 1880, an assessment (No. 6) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, Safe Deposit building, 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Seventeenth day of February, 1880, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the Ninth (9th) day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. W. PARRISH, Secretary.

Office—Room 7, Safe Deposit Building, No. 328 Montgomery street, San Francisco, California.

Gover Mining and Milling Company.—

Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

Notice is hereby given that at a meeting of the Directors held on the 24th day of December, 1879, an assessment (No. 40) of ten cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the company, No. 402 Front street, room 8, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the second day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday, the First day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

W. O. WILSON, Secretary.

Office—402 Front street, room 8, San Francisco, California.

Rocky Point Mining Company.—Location

of principal place of business San Francisco, California. Location of works, Placer County, California

Notice is hereby given that at a meeting of the Board of Directors, held on the Fourteenth day of January, 1880, an assessment (No. 2) of Ten Cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. Gold coin, to the Secretary, at the office of the Company, room 1, No. 314 Bush street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 20th day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Thursday, the 11th day of March, 1880, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors

A. C. TAYLOR, Secretary pro tem.

Office, 314 Bush street, San Francisco, California.

Of Immense Practical Value to Every Saw User.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Large Octavo. Over 150 Illustrations.

By ROBERT GRIMSHAW, Ph. D.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, sash, Muley, jig, drag, circular, cylinder and band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 96 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed.

Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the subscription price is this date made $2.00, postage paid, up to date of publication, after which time full retail price will be charged. In press. Orders received now at subscription price, $2.00.

ROBERT GRIMSHAW,
624, 626 and 628 Market Street, Philadelphia.

January 1, 1880.

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

GOLD SAVED!

Very Important to Quartz Mill Men!

Silver Plated Amalgamating Plates,

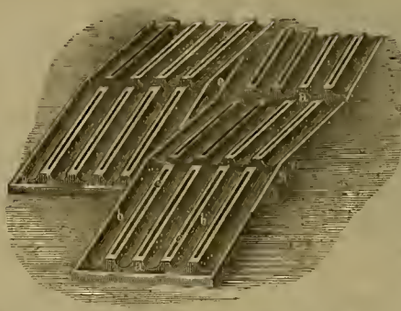
For Saving Gold; supplied in any quantity and size at Lowest Possible Rates, and Satisfaction Guaranteed.

PACIFIC GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

41 Geary St., San Francisco

W. E. SHEPMAN, - - - PROPRIETOR.

Howland's Under-current, Mill and Sluice Riffle.



This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

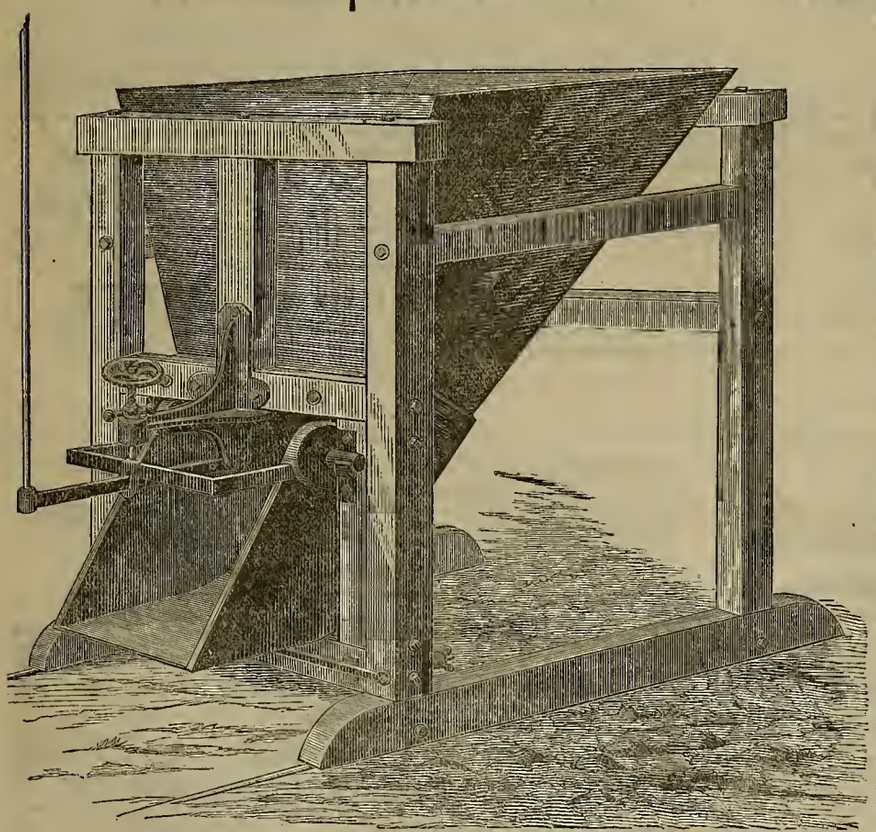
DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Price Reduced to $75.

NOW IS THE TIME TO BUY CHEAP ORE FEEDERS!

The Improved Stanford Ore Feeder,



Next best in the market to the famous

Challenge Ore Feeder,

Can now be bought for $75 each. It is in use in many mills on this coast, and wherever used gives great satisfaction.

The STANFORD and CHALLENGE Feeders, made by me, have superseded the Victor Ore Feeders, furnished by E T Stoen, in the Alexander mill, J. B. Cooper, President, office, Safe Deposit Building, S. F.

In this connection I will state that I will give $50 to be shown up to this date one of the Eclipse Ore Feeders, manufactured by Prescott, Scott & Co., of the Union Iron Works, which is at work satisfactorily at any quartz mill on this Coast.

I have made a specialty of manufacturing

Ore Feeders

And know which will give satisfaction for steady work. This Improved

Stanford Feeder

Which I sell for

$75.00

Will beat any one in use—always excepting the CHALLENGE, which is

MINING AND SCIENTIFIC PRESS.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO., Publishers.

SAN FRANCISCO, SATURDAY, FEBRUARY 7, 1880.

VOLUME XL Number 6.

Our Silver Mines Should be Fostered.

Ours is a silver-prodncing country. That metal is as mnch one of the products of the soil as is wheat or potatoes. Its production has assumed such great proportions and given employment to so many people that it has risen to the rank of a national indnstry. As such, it should meet with all the fostering care which it is possible for govcrnment to bestow upon it. By so doing, it adds to its own welfare. It angments its own wealth. It stimulates a wide field of labor for its citizens to occupy, from the product of which they are enabled to pay for such foreign articles as arc not produced at home.

Tho government stands in relation to this industry the same as a farmer does to his wheat field. If the latter neglects it, if he does not see that it is well cultivated, that good seed is cast into the soil, and that the crop is carefully garnered; instead of deriving an iucome from it, he will find that it entails a loss to him. He would he considered hy his more judicions neighhors as heing devoid of wisdom and economic management. The great financial countries of the world do not produce silver. But when they obtain it in payment of what they do prodnce, they ntilize it as a medium of interchange among their own people. Their laws are enacted with this purpose in view. They retain as far as possible their metallic currency within their own limits. By this judicious course they make their own products add indireotly to their financial facilities. But it would seem as if our government has determined to throw all possihle ohstructions in the way of the progress of this important iodustry. It demonetized silver, thus depreciating its value and forcing it down to the lower grade of more common metals. It was reduced from a measure of value to a mere article of merchandise. The fall in its value entailed a loss of millions of dollars in silver alooe; and of consequential loss through the disturhance of financial and commercial transactions of a still greater amount. In this case it had sown bad seed, and neglected to properly cultivate the field or carefully garner the crop. It evinced a sad lack of executive ahility. And even now instead of aiding in its circulation, and thus opening a wide channel for its use, its operations are of a restricting character, and retard instead of advancing the great silver industry which should he judiciously nurtured. It discriminates against a leading source of its own wealth.

Every movement that has a tendency to promote the use of silver; every new chaunel that leads to an increased consumption of it; every encouragement tnat can he afforded to this industry should he followed up with promptness and decision. Every dollar's worth of silver taken from the mines is a dollar added to the national wealth. If it cost teu dollars to produce that one, the ten dollars cost is not lost to the nation; it has only changed hands from one citizen to another. It has paid for labor, for supplies or for material. It may have weakened the resources of one person, hut it has added to the resources of others. It still exists. It is not annihilated. Added to it is the one dollar which it has produced.

The principles involved in the silver question are applicable to all hranches of mining. They should be fostered by carefully digested statutes whose operative influence should he in their favor. Until this is done, all mining operations will he hurdened to the extent of the adverse policy which is pursued in regard to them.

MINING SUIT.—One of the first and most important cases to come up in the United States Circuit Court as soon as jury cases are taken up, is that of the North Noonday Mining Co. against the Orient Mining Co., to quiet title to mining property in Bodie district. The Orient is now in possession of the property, and the Noonday aeeks to eject them. It ia estimated that the trial will last several days, perhaps extending into weeks.

JACK CARLTON, chief of sconts with Howard's command in the Nez Perces war, was accidentally killed recently near Walla Walla, W. T.

Magnitude of Labor.

Tbere is nothing that has ever attained the vast proportions that lahor has acquired. It extends over the cntire glohe, so far as the operations of man are concerned, and throughout the seemingly unlimited realms of space, under the exertions of the Omnipotent Creator. Leaving out of consideration the wondrous array of stellar systems, and narrowing the view to the work of the human race, the field is still too ample for a detailed narration. It can, even in this scope only, be treated of in generalities. The animals lahor, hut it is only to the extent of self-preservation. The heaver huilds his dam across the running stream; the hirds construct their nests in the hranches of the trees; the burrowing animals dig into the surface of the earth; and the insects spin their wehs or construct their fragile colls—eacb and all guided hy the natural law of permeation of their progeny.

The lahors of man extend to a higher and oohler plane. Originating in self-preservation and protcction of offspring, they have risen to the more elevated rank of a creative power, which has encompassed the earth and left no spot upon its surface undisturhed hy their multifarious results.

In every phase of social life labor holds the sole sustaining influence, deprived of which the fabric of society would meet with annihilation, and man descend to a scale below the heaver and the hird in practical utility. In the advancement of the well-heing of the human race, lahor has ever been the motive force which has accelerated its progress. It has stimulated the intellect, and conferred aptness upon muscnlar manipulations. It has given ideas to the hrain, and deftness to the hand. Its rcsulta have pointed out new methods of attaining them, which have required lesa muscular action and more hrief periods of time, with greatly increased results.

Nothing can he effected without lahor; with it, all things can he accomplished. When in operation, it is vitality; when inactive, it becomes inertia and death. It crosses continents in its gigantic strides, steps over oceans and traverses the globe, carrying witb it beneficial results, and imparting as it goes, ardent desires for a continuing increase of its hlessings.

It points out the track of the seemingly erratic comets; it maps out the path of the sun, moon and stars; it measures the far-distant worlds, and weighs them with positive accnracy. It has constructed instrnments hy which their constituent forms of matter are made known. It overleaps the confines of the earth, and extends its efforts to the remotest regions of stellar existence.

It razes mountains to tbe level of the plain, or cuts its passage through miles of their hase. It deepens rivers, fills up lakes, makes fertile the desert. Earth is hut one of the compartments of its workshop, and in every section of that compartment it demands and compels activity. Its avocations are unlimited, extending from the least to the greatest prodnctions, from the sharpest point of a needle to the massive form of the pyramid; operating upon tbe formations of bodies almost too fragile to be touched, and working upon others of adamantine durahility.

It is a magnificent temple of God-like proportions, so vast, so extended that it embraces the whole realm of creation; so perfect in its construction that defects are unknown; so enduring in its material, that it will still exist when earth shall have passed away; so wisely planned that heauty and harmony are presented at every point, and its resultant will he the advanced welfare of man. Omniscience only could have invested lahor with its grandeur and greatness, and have stored it so fully with henefits and hlessings. Its dome rises to the highest heavens and is lighted hy the stars; ita walls contain all created matter, and its foundationa rest upon unswerving utility. Into this vast hall all must enter and perform their task, which to some will he hard to accomplish, to others, easy of performance. There is no exemption from this duty. Even those that are termed idlers and drones, work in their peculiar way to teach to others the evils of indolence, and in their own self-condemnation have the most irksome task of all to sustain.

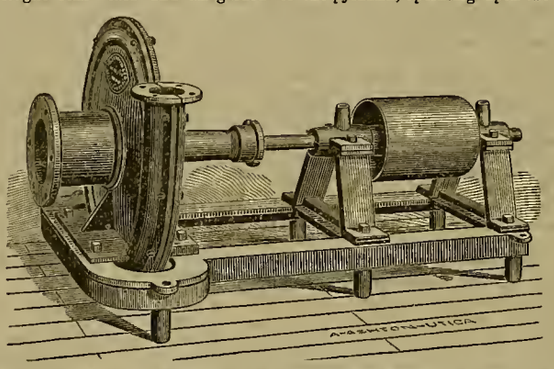

FIG. 1. PERRY CENTRIFUGAL PUMP—HORIZONTAL STYLE.

Fig. 2. Section of Piston.

METEOROLOGICAL SUMMARY FOR JANUARY.—The report of the United States Signal Service officer, of San Francisco, for the month of January, is summarized as follows: The mean hight of harometer for the month was 30.143; mean temperature, 47.8; mean humidity, 74.8; prevailing winds, north; highest harometer, 30.449; lowest, 29.765; highest temperature, 60°; lowest, 37°; monthly range, 23°; greatest velocity of wind, 36 milea per hour; total number of miles traveled hy wind, 4,622; total rainfall, 4.78 inches. Rainfall in January during former years: 1872, 4.03 inches; 1873, 1.58 inches; 1874, 5.66 inches; 1875, 8.01 inches; 1876, 7.55 inches; 1877, 4.32 inches; 1878, 1.97 inches; 1879, 3.52 inches.

NEAR Barcelona, Spain, a rich landowner, his wife, three daughters, son and two women servants were murdered in their beds, and the house ransacked.

THE Pacific Mail Steamship Co. have reduced their passenger rates to $75 in the cabin and $35 in the steerage.

The Perry Centrifugal Pump.

We give on this page an engraving of one style of the Perry centrifugal pumps, whicb has gained an excellent record at the indnstrial fairs at tbe East, and is in good repnte among those who have used it for various purposes. Tbe claim of the inventor is in the simplicity of the device, and the consequent cheapness and dnrahility in the machine. There are no valves and therefore mud, sand, gravel, or any otber substance liahlc to get into pumps when used for irrigation or in connection with manufacturing, will be carried out with the fluid, and occasion no stoppage. There are no irregular surfaces, consequently the flow of the liquid is unimpeded, and friction heing reduced to a minimum, the highest percentage of effective work is realized from the power applied. These facts adapt the pump to the emptying of dry docks, contractors' excavations, drainage or irrigation of lands, as well as elevating water in large quantities for any purpose.

There are two main styles of the Perry pump, called "vertical" and "horizontal," according to the positions of the shaft when on duty. The engraving, Fig. 1, shows the plain horizontal pump No. 2, fitted to an iron bed frame, ready to he put in operation. The flange upon the left is ready to he holted to a tank or flume when the water or other material to he raised is on a level with the top of the pump at the commencement. It will continue to act efficiently as long as the material can fill the injection pipe leading into the pump. When it is necessary for the pump to raise its own material, there is a suction attachment affixed to this flange on the left.

In order to show the simplicity of the piston used in the Perry pump, we show a sectional drawing at Fig. 2. It will he seen that it consists merely in a wheel composed of a center huh and from four to seven wings, according to the size of the pump. These wings are curved in such a manner as to give the greatest outward pressure to the fluids passing through it. The one shown in the engraving is hottom side up, showing the upper half of the shell or soroll, also presenting to view the sharp edges of the wings near the huh, and corresponding in extent to the size of the orifice in the hottom of the pump. The object of these sharp edges is to admit of the free ingress of the fluid, and also to cut any foreign substance that may enter the pump, thus preventing its becoming choked nr clogged.

These pumps are adapted to raising water to various hights, as the elevation is of conrse dependent upon rate of speed at which the pump is driven. The capacity is provided for hy different sized pumps, ranging from a delivery of 260 to 20,000 gallons per minute. Full information concerning the meehanism of the pump, its appliances and its working quality can he obtained from H. P. Gregory & Co., No. 4 California street, S. F., who are the agents for this coaat.

BIG SUBSCRIPTION TO THE IRISH RELIEF FUND. The New York *Herald*, after calling attention to its tahles showing the Irish distress, says: "In making this apneal to the henevolent, we deem it fitting to set an example which will he taken as proof of our sincerity. The *Herald*, thcrefore, opens a subscription for Irish relief, heading it with the sum of $100,000." It solicits other people to give in proportion to their willingness and means. It will receive subscriptions for any amount down to 25 cents, carefully puhlishing the name and residence of every aubscriher, and, when desired, the place of his former residence in Ireland, that the people relieved may know to whom tbey are indebted.

THE NEW IDRIA PATENT AT LAST.—On the 30th ult. a patent was signed and delivered at Washington to the New Idria mining company for the Panoche Grande quicksilver mine, in California. The application of the New Idria company had heen amended so as to conform with Secretary Schurz's opinion, puhlished in July last.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

Globe District, Arizona.

EDITORS PRESS:—Globe district is still moving along. Considerable machinery that I spoke of in my last has arrived, so that the building of roads, grading of mill sites and taking out ore keeps every one busy, proving the old adage true, "A contented mind is a continual feast." I haven't, since my arrival here, a year ago, noticed the same feeling of industry that there is at present.

Every one, who a few months ago thought they had a fortune buried in some claim, and were waiting for some one to come along and buy them out at a small figure, have now gone to work to open and develop so as to realize something handsome. The idea is now pretty thoroughly exploded that our mines won't go down, for those who have the means to go down have the finest property in the camp, and are refusing big money for them. The owners of the Emiline have struck it good. Two tons which were reduced by the Isabella mill returned over $300 per ton. Yesterday they were taking out ore showing native silver which will probably pay shipping to your city for reduction. This claim is located on the same vein with the Bluebird and Danube, and between the two, proving beyond a doubt that all three are valuable.

I promised in my last to send you some items from our gold belt, as I thought at that time I could send more mill returns, but am sorry to say that the repairing and getting the mill ready occupied more time than was thought, so must leave it until my next. I am only writing about what I have visited and examined, taking no one's report for granted, so I am not liable to be led astray. A trip two or three times per week on a good mustang through the district keeps me pretty well posted.

We have the finest climate here that I ever saw, more especially in the winter; three or four cold stormy days and all is fair again. Yesterday I found an ordinary coat uncomfortable while riding in the afternoon. There is no fog; the nights are clear and cool, making it just right, neither too cool nor too warm.

We have a promise from Wells, Fargo & Co. of an express office, and without doubt will soon have the telegraph at our door.

The A. T. & S. F. R. R. are talking encouragingly, and have sent their engineers through here to hunt a route. This, together with our late sales has stimulated and started many, who a few months ago were despondent, so that Globe is liable to have a "boom" before long that will surprise some who have given her the cold shoulder.

One thing I have noticed in particular is the men coming into town. It used to be the custom to stop and visit awhile, but now it is hurly burly, gather together their tools and provisions, and off they go, showing that there is something more enticing in the hills than heretofore. Some splendid reports come from the Richmond basin, almost too good to be true; but must close, with more anon. MINER.

SALT FOR THE MILLION.—Surveyor L. D. Bond estimates the area of the great salt deposit across here in Saline valley to be about 1,200 acres. Over the greater portion of these broad acres lies a bed of pure, solid salt, full 18 inches in thickness. A portion of the central part is either covered or completely saturated with water; most, if not all the salt being taken from this marsh for use throughout this section, is shoveled out of this saturated portion; in so doing excavations nearly two feet in depth are made in the solid sheet of salt, which excavations, of course, fill with water clear and apparently pure. In three or four days' time crystallization goes on so rapidly as to renew the deposit as deep and solid as before it was disturbed, and will continue to do so indefinitely. There is salt enough there to pickle the whole animal creation of the world, humans and all. In the same valley is another smaller but very similar deposit of impure salt and borax crystals in nearly equal proportions. This valley is about 25 miles, as the crow flies, easterly from this town.—*Inyo Independent.*

KILLED BY A METEOR.—As David Meisenthaler, the well-known stockman of Whitestone township, was driving his cows to the barn about daylight this morning, he was struck by an aerolite and instantly killed. It appears as if the meteor had come from a direction a little west of south, and fell from an angle of about 60 degrees, for it first passed through a tall maple, cutting the limbs as clean as if it had been a cannon ball, and then struck him apparently on or under the shoulder, passing clean through him obliquely from below the right shoulder to above the left hip, and buried itself about two feet in the soft black ground. The poor man's head and legs were uninjured, but the greater part of his body seems to have been crushed into the earth beneath the terrific aerolite, which is about the size of a common patent bucket, and apparently of a rough round shape. It appears to be formed of what is called iron pyrites.—*Bucyrus (O.) Journal.*

Prehistoric Man.

When did Man Make his Appearance on the Pacific Coast?

The following article, by the Hon. B. B. Redding (Reno *Gazette*, Dec. 31st, 1879), deals with a subject which cannot fail to interest all who look beyond their own lives to the life of the human race—all who long to pierce the veil that shrouds the origin of man.

In no part of the world is there so good an opportunity to gather facts as to the extent of time that man has been an inhabitant of the earth, as on the Pacific coast. Prospectors and miners are at work in all directions. Hydraulic miners are washing down hills; drift miners are delving at the bottom of extinct pliocene rivers; prospectors for gold, silver and cinnabar are turning up the surface in all probable and improbable places, over an area of at least 16,000 square miles; and farmers plow up the burial places of prehistoric man, and enrich their gardens from the shell mounds and kitchen refuse of a people who had disappeared from the earth countless ages before Abraham and Lot divided Palestine into sheep ranges. All of these people find frequent evidences of the work of prehistoric man. Instead of being saved and placed in some public institution, where they can be preserved, studied and compared, they are either left where found, or adorn some bar-room collection of quartz crystals, pyrites of iron and silver ores. There is no archæological society on the Pacific coast; even

"The Society upon the Stanislaus"

Has become extinct. The total collections of the work of prehistoric man of the Pacific coast, in the California Academy of Sciences and in the State University, will number but a few dozen mortars, obsidian knives, scrapers and arrow-heads, while the Smithsonian Institute, the French Ethnological Institute, Harvard University and the British Museum contain collections that may be measured by the ton. If miners and farmers on the Pacific coast who turn up mortars, spear-heads, or other works of man, made from stone, would send them to the Academy of Sciences, or to the University, with a short account of the place where and the circumstances under which they were found, the archæological student would not be compelled to visit the Smithsonian or Harvard collections to obtain the means of comparison between the works of the people found here by Father Junipero Serra, and the race that lived on this coast before Shasta, Lassen Butte, and other now extinct volcanoes capped the Sierra with sheets of lava, or with those of a still more ancient people, who hunted and fished among the foothills of the Sierra when these hills were washed by the waters of the Pacific ocean—probably long before the Coast range of mountains made its appearance above the sea.

When Shasta and Other Volcanoes

Were pouring out lava, filling up the ancient river channels, forming our hydraulic mines, and causing a new system of drainage for the Sierra, the volcanoes of the Cascades in southeastern Oregon were sending out ashes, filling up the lakes, and making fossil the camel-llama, the one-toed horse, the saber-toothed tiger, and other animals that then roamed over that lake country. Vesuvius, in historic times, covered Pompeii and a region about five miles square with ashes. Southeastern Oregon is covered with volcanic ashes over an area of more than 200 square miles.

The evidence is beginning to accumulate that man lived in this, then lake region, of southeastern Oregon, contemporaneous with the fossil horse, the camel-llama and other animals now extinct. In Big Bone prairie, in the Silver Lake region, in connection with the remains of these animals, Prof. Cope's men lately found arrow-heads, and so-called spear-heads. These differ in form from any now used by California or Oregon Indians. These so-called spear-heads are flakes of obsidian of various lengths, from 5 to 12 inches, chipped into a long, oval form, pointed at both extremities, sharpened at the edges, and varying in thickness at the thickest part—dependent upon the length—the smallest being a half-inch, and the largest an inch. Whatever the size, the form and proportions are always relatively the same. They were probably not spear-heads, as, if used for this purpose, there would be no object in sharpening both extremities. They were probably knives used for some special purpose. The oldest living California and Oregon Indians do not use them, and do not know what they were for. The McCloud Indians

Still make Stone Knives,

Scrapers and arrow-heads, but nothing of this form. None of this kind have been found in the shell mounds or burial places of Pacific coast Indians, and some of the "kitchen middens" of the coast of California, must have been thousands of years in accumulating. They have never been found in California, except, below the boulders in hydraulic mines, at the bottom of extinct pliocene rivers, or below the auriferous earth and gravel of placer mines, and, as stated lately by Prof. Cope in Oregon, in connection with the fossil bones of extinct animals. There are two of these spear heads in the Smithsonian collection, one from the hydraulic mines of Calaveras county, and the other, numbered 7,342, from Folsom, Sacramento county. This spear head was found, with a disk of slate, having a hole in the center, on a ledge of granite, at the bottom of the gold mines, 23 feet below the present surface of the streets of the town of Folsom. About 30 feet below the streets of Folsom, the miners find a bed of hard, salt-water mud, filled with fossil oyster shells, and shells of the extinct crustaceans of what Clarence King calls the miocene ocean. This ledge of granite is a point from the foothills of the Sierra that jutted out into this ancient sea. Who were the people that hunted and fished along the foothills when the bass of the Sierra was washed by the ocean? Was the top of Diablo then an island? Or was the

Sacramento Valley an Island Sea

Like Puget sound or the Black sea? It is not singular that more of the spear-heads of these primeval people are not found, or that when discovered they should be found beneath the drift and boulders of our gold mines. If any were left on or near the present surface, and had been discovered by the ancestors of our present Indians, they would have been split into knives and arrow-heads, for obsidian in any form was of the first necessity, and the most valuable material in use until white men brought iron to the coast. So far as I can learn, there are five of these peculiar spear-heads in public institutions, two at the Smithsonian, two in the possession of Prof. Cope, and one at Harvard. There are probably dozens in miners' cabins, or ornamenting bar-rooms in the mountains, or used as paper weights in village grocery stores in California and Oregon, which, if they could be gathered in some public institution, with the facts and history of their discovery, would go far to prove that man made his appearance on earth, and lived on this coast when the mastodon, elephant, cave bear and saber-toothed tiger wandered among the foothills of the Sierra, or, perhaps earlier still, when the earth had so far evolved from hot chaos as to develop a climate that would give him food and provide him with shelter.

The Debris Question.

Certain Dutch Flat miners have a plan for solving the Bear River debris question which, though extensive, seems practical, and therefore worthy of thorough consideration. It is proposed by them to run a tunnel from the bed of Bear river through to the North Fork canyon, at a point a little above Colfax, Cape Horn, and through this tunnel divert all the debris that otherwise would flow down to harass and injure the Bear River farmers. A tunnel for this purpose, with sufficient grade, would be about 11,000 feet long, and would enter the North Fork canyon from 500 to 700 feet above the bed of the latter river. The estimated cost of this tunnel is between $250,000 and $300,000. By means of such an outlet the accumulated tailings in Bear River canyon, which amount to many millions of cubic yards, could be washed out, and according to the estimate of a competent engineer, these tailings alone contain from $25,000,000 to $30,000,000. Thus this project not only affords a solution to the Bear River debris question, but opens up at the same time one of the most extensive mining enterprises in the world. It is suggested that such undertaking would not necessarily interfere with the rights of ditch owners who divert their water from Bear river below this point, as in the summer time when no mining is going on the tunnel could be stopped and all the water retained in the Bear River channel for the benefit of these ditches, and in the winter, when water is plenty, enough could be diverted from the tunnel and sent on down the old channel to keep the ditches full. Another point, however, might seem more difficult to overcome, and that is the objection which Sacramento and the people on the American river would naturally interpose to any project which threatened to heap on their shoulders, as it were, in addition to their present burdens in the debris line, the accumulations which now weigh so heavily on the farmers of Bear river. This objection it is proposed to meet by the construction of a dam high enough and strong enough in the North Fork canyon, at a point below Colfax, to hold all the debris that would ever be conveyed in that channel through the proposed tunnel. Such a dam as would be necessary, it is thought, can be constructed at a comparatively small cost, by tunneling into the side of the gorge, at a point where the canyon sides are precipitous, and then by means of sufficient powder fired by electricity, blow the whole side of the mountain down into the river. This plan is original and novel, and yet old miners accustomed to heavy blasting pronounce it entirely practical. A dam thus formed would be superior in strength to anything constructed by tamer means, as it would be composed entirely of rocks, many of which would be so massive that no ordinary body of water could move them. The project is a stupendous one, but if it can be made successful, and we believe it can, it will virtually solve the debris difficulty, so far as relates to Bear river and the North Fork, and at the same time open up additional mining enterprises, compared with which the largest gravel mines now known would be but small affairs.—*Placer Herald.*

FROM a yield of $100,000 in bullion in 1865 the Georgia gold fields have advanced to $1,000,000 per annum, with a promise of large returns this year.

GREAT activity is apparent in the German iron and coal trades.

Desulphurizing Pyritous Ores.

A slow roasting of the ores at a dull, cherry-red heat partially accomplishes the removal of the sulphur, but it still allows a sufficient quantity to remain, to prove detrimental to a perfect desulphurization. This evil is felt in the working of lead and copper ores; it is still more apparent in the reduction of iron ores, and it produces disastrous results in the amalgamation of gold ores.

In the reduction of iron ores, if the sulphur is not entirely removed, it renders the iron brittle. In working gold ores the presence of the sulphur prevents, to a marked extent, the disintegration of the gold by the quicksilver, which forms the amalgam.

Among the iron workers a method of overcoming the difficulty has been earnestly sought for, but has not yet been found. The iron deteriorates in quality in proportion to the amount of sulphur combined with it. They have used a basic slag with good effect in absorbing the sulphur, but it has not accomplished the perfect extraction of it from the iron.

It requires more oxygen to overcome the presence of the sulphur than it can obtain by an ordinary roasting process. To provide for its complete removal from the ore, it must be brought into contact with an excess of oxygen, and any substance which can yield this excess, will affect the desired result. Nature has placed such a substance in the reach of all miners. It is to be found in every section of the world, and if not in every mining camp, it certainly can be procured in the near vicinity of all of them. This is the common limestone, which is, chemically speaking, an oxide of calcium. If, therefore, in the roasting process of ores containing sulphur, a liberal quantity of limestone is mixed and roasted with them—care being taken to keep the heat within the limits of a dull cherry-red—the reaction upon the limestone will liberate the required oxygen and the combustion of the sulphur will be perfected.

The carbonate of the oxide of calcium, or burnt lime, as it is popularly termed, will not interfere with the after process of either smelting or amalgamating, but will, in reality, rather facilitate the operation of both of them. The ore and the limestone should be crushed to a fine powder and thoroughly intermixed before being roasted. They should be freely raked while roasting.

Tulare Lake Water Alkaline.

Prof. Hilgard informs us that since his announcement at the December meeting of the Horticultural Society, of the alkaline quality of Tulare lake water, he has accurately determined the matter in solution in the water, and finds it far more alkaline than preliminary tests led him to suppose. He finds now that there are 84 grains of mineral salts dissolved in each U. S. standard gallon of water, and that 31 grains are carbonate of soda, the balance being chiefly common salt and glauber salts. In potable well water the largest amount of mineral salts is about 15 grains to the gallon, and in ordinary river water from 8 to 12 grains is the highest. Thus it appears than in Tulare lake water there is not only six or seven times as much mineral matter in solution as in well or river water, but the matter is wholly different in the lake water, being in great part of caustic alkaline character, and destructive to plant life. This water, although its alkaline salts could be neutralized by the use of gypsum, would require large amounts of the latter, say about 150 pounds of gypsum for every inch depth of water put upon an acre, or 1,500 pounds per acre, if ten inches of water were applied to irrigation. Even with this treatment it would not do to put on so much water and allow it to evaporate from the surface, because of the deposits of salts which would take place, and even with the remedy suggested there would have to be drainage planned, and perhaps more water applied to wash out the objectionable matter from the soil. Thus it clearly appears that there are chemical as well as engineering problems to be considered in irrigation schemes, and it is fortunate that the College of Agriculture has called attention to the Tulare lake water before the public money was devoted to carrying out an enterprise which might be a triumph from an engineering point of view, and yet worse than useless to the agriculture of the region. Of course we do not say that this would ultimately be the case if the West Side scheme were carried out, for the rivers emptying into the lake may be wholesome, and the alkaline supply of the lake be guarded against. But this and all correlative points must yet be determined, and it is plain that the inquiry must take a wider range than heretofore supposed before the investment on the part of the public can be considered a safe one.—*Pacific Rural Press.*

NEW TARIFF ON ORES.—The reduced tariff on ores on the Southern Pacific railroad, which went into effect on the 1st of January, is as follows: Ore not worth over $100 per ton is $12 per ton from Casa Grande to San Francisco; for ore worth over $100 per ton 2% additional will be charged on the increased valuation. These are very low rates, and we have no doubt our miners will avail themselves of the low tariff. We have already heard of quite a number who contemplate making extensive shipments as soon as the road reaches the city.—*Arizona Star, Jan. 15.*

MECHANICAL PROGRESS.

Tempering Steel Springs.

Tempering to impart to steel its maximum of elasticity, is a branch of the art requiring, to obtain the best results, the most expert of manipulation. This is especially the case where the springs are subject to severe strains in proportion to their dimensions, while at the same time subject to vibrations. Under these conditions the least degree of undue hardness causes a spring to break, while undue softness causes it to bend to a permanent set, thus altering its normal form. For instance, if a spiral spring, whose coils are distended by force applied at the ends, "sets," the coils, when released from distention, will not approach each other to the distance they did before distention, the amount of difference being the amount of the "set." Or, if the coils were compressed and failed when released to resume their natural positions relative to each other before compression, the spring has "set." Hence the relation between the length, breadth and thickness of a spring, and the nature and amount of its duty are vital elements in estimating the quality of its temper.

The commonest method of spring tempering consists in first hardening the steel, and then blazing it off by heating it in connection with some fatty combustible compound, which will take fire and blaze when it has acquired a certain temperature, it being found that the temperature at which heavy oils, tallow, etc., take fire is about that necessary to reduce a well-hardened spring to the degree of temper imparting to steel its greatest elasticity.

Here we have two separate operations, hardening and tempering; and to avoid this, and temper at once, without the intervention of hardening, is an object of great importance. It has been accomplished, however, in several cases. Thus, one of our largest spring manufacturers tempers spiral springs as follows: They use Gregory's crucible steel, heating it in a furnace burning gas coke, but the furnace has a return flue and heating chambers, and ovens between the flues, the heat passing through the brick-work forming the flues into the ovens. To facilitate renewing the ovens (which, of course, also renewe the flues), the floor of each oven (which forms the ceiling of the oven below), is built on iron supports, protected by the brick-work and suitable fire clay, the bricks all being made to pattern, thus involving very little labor in building. The furnace doors are at the ends, and are kept closed as much as possible. In this way the steel has no contact with the products of combustion of the fuel, and the air is excluded as far as practicable (two valuable features). The furnaces are long and narrow, and not being connected with the flue there is but little disposition for the cold air to rush in when the furnace doors are opened.

The hardening and tempering of springs whose coils are of thick cross-section is performed at one operation as follows: The springs are heated in the furnace or oven described, and are first immersed for a certain period in a tank containing fish oil (obtained from the fish "moss bunker," and termed "straights"), and are then removed and cooled in a tank of water. The period of immersion in the oil is governed solely by the operator's judgment depending upon the thickness of the cross-section of the spring coil, or, in other words, the diameter of the round steel of which the spring is made. The following, however, are examples:

Number of coils in spring	5¾
Length of the spring	6 inches
Outside diameter of coils	4¾ "
Diameter of steel	1 inch.

The spring was immersed in the oil and slowly swung back and forth for 28 seconds, having been given 35 swings during that time. Upon removal from the oil the spring took fire, was redipped for one second, and then put in the cold-water tank to cool off.

Of the same springs the following also are examples:

Example.	Time of immersion in oil.	Number of swings in oil.
Second	36 seconds.	46
Third	27 "	36
Fourth	33 "	40

SIZE OF SPRINGS.

Number of coils in the springs	6
Length of the springs	9 inches.
Inside diameter of coils	3¼
Size of steel	1×1½ square.

Example.	Time of immersion in oil.	Number of swings in oil.
First	9 seconds.	12
Second	8 "	12
Third	8 "	12
Fourth	9 "	12
Fifth	9 "	12
Sixth	9 "	12

To keep the tempering oil cool and at an even temperature, the tank of fish-oil was in a second or outer tank containing water, a circulation of the latter being maintained by a pump. The swinging of the coils causes a circulation of the oil, while at the same time it hastens the cooling of the spring. The water tank was kept cool by a constant stream and overflow.

If a spring, upon being taken from the oil, took fire, it was again immersed as in the first example.

In this, as in all other similar processes, resin and pitch are sometimes added to the oil to increase its hardening capacity if necessary.

The test to which these springs were subjected was to compress them until the coils touched each other, measuring the hight of the spring after each test, and continuing the operation until at two consecutive tests the spring came back to its hight before the two respective compressions. The amount of set under these condition is found to vary from three-eighths of an inch, in comparatively weak, to seven-eighths of an inch for large, stiff ones.—*Joshua Rose, M. E., in Wheelwright and Blacksmith.*

Machine Work in English Shops.

Mr. Wilson Hartwell, in a paper read at a meeting of the Leeds Association, recently, discussed the necessity of measuring from time to time the performance of the tools and machinery for producing engineers' work, and gives some very interesting figures shewing what he considers the average standard performance for various descriptions of work, which may be looked upon as representing fairly the work of the best English shops.

One of the most important items of cost is the rate at which the work is tooled. This rate depends more upon the extent of the surface than upon the quantity of material to be removed. For in most cases it can be removed at one cut, and the speed of cut is not much affected by the depth. Where two cuts are needed, the finishing cut should be as light as possible, with a broader advance.

For comparing the time required to tool various surfaces, it is necessary to reduce it in each case to the same unit of surface and of time, such as the number of minutes required for tooling a square inch or a square foot, or the number of square feet or inches done in an hour. The numbers thus deduced have a constant value for all work tooled at the same speed with the same width of cut, and hence are called "constants."

Constants, therefore, furnish the readiest means for estimating the time required to tool similar surfaces similarly situated, but of different dimensions. In choosing a constant for office purposes, such as for estimating, arranging piecework, etc., the time in minutes required to tool a square inch would do as well as any other. But for practical use in the workshop, where rapid mental calculations are required, these constants are too small in value, and involve the use of numbers too high to be convenient. A more useful constant is the number of square feet that can be tooled in one hour; such are those shown on all the tables.

The best way to ascertain constants is to note the speed of cutting and the number of such cuts per inch in width. To find the area in feet tooled per hour, divide five times the speed by the number of cuts per inch. The "advance," or the number of cuts per inch, should be observed by actually counting the cuts in one inch, or fraction of an inch. (If the advance be too fine to be readily counted, it is too fine for ordinary work, and should be altered.) The speed in feet per minute equals five times the speed in inches per minute. The actual speeds vary much in practice, but the ordinary variations are far greater than necessity requires. In cutting wrought iron it will be readily admitted that a speed of 15 feet a minute can be maintained under nearly all circumstances; 20 feet will perhaps be admitted; 30 feet probably denied. The speed is chiefly limited because the tool gets warm. With an abundant stream of soapy water supplied by means of a pump, 30 feet has been maintained; with water supplied under the cutting edge, 45 feet in a short experiment; with heavy tools and a jet of water 1-16 inch in diameter, supplied from the town water works under pressure, 20 feet to 25 feet per minute. The ordinary lathe, with ordinary conveniences, however, has a speed of 20 feet per minute. For cast iron, 16 feet per minute may be assumed.

The advance varies from 1-16 to 1-80 on small work, often simply at the whim of the turner or the chance accident of the feed gear. The greatest loss of time is due to using an advance much finer than repeated experience has shown to be necessary. All roughing work above 3 inches in diameter, with a second cut to follow, can be done at one-eighth inch advance. If the work is to be finished at one cut the 1-16 inch advance could be used for all sizes above 2 inch, but 1-16 inch to 3 inch, 1-24 inch to 2 inch, and 1-32 inch under 2 inch has been taken.

THAT SOUTH AUSTRALIA HARVESTER PRIZE. We have not heard much of late concerning the competition for the $20,000 offered by the South Australian government for a single machine that would successfully cut and thresh grain at one operation. We notice that a writer in the Adelaide *Observer* takes the ground that at least six animals would be requisite for drawing such a machine, and that "the weight and power of even five horses is a serious matter. They batter the ground badly and are expensive, etc." We would like to know what the South Australians expect. This correspondent talks as though by combining a reaper and thresher, there ought to be such power gained that half the animals required on the two would suffice. This is rather out of the line of mechanical experience. Our operators of combined headers and threshers use a score of horses or mules, and yet think they have money over the old way of harvesting. If our South Sea neighbors are so prejudiced against horse power, they had better go back to the cradle and flail, and put their prize money out at interest.

MOTIONS OF THE GROUND.—It will be remembered that M. Plantamour directed attention some time since to certain displacements of the bubble in a fixed spirit level, indicating movements of the ground. He has now made a year's observations of these phenomena in a cellar at Secheron, with two spirit levels, one directed north and south, the other east and west. The result is the manifestation of periodic movements of rise and sinking of the ground, which, in a general way, appear to be determined by the exterior temperature. After that the configuration, and, perhaps, also the nature of the ground, probably affect the intensity of the movements.

ALUMINIUM TELEGRAPH WIRES. — German telegraph engineers have lately been experimenting with aluminium as a material for telegraph wires. This metal can easily be drawn out to a very much finer gauge than is possible with iron, and its conductibility is twice as great as that of iron wire. Its excessive cost has hitherto prevented its use for the purpose indicated, but it is found that an alloy of aluminium and iron can easily be made, which will produce a wire both finer and stronger, and less susceptible to atmospheric changes than iron wire, while it is much superior as a conducting medium.

PREPARING STEEL.—A novel mode of preparing steel has been suggested by Signor Guido, an Italian engineer. It consists in electrolyzing water by means of a dynamo-machine, and smelting the carboniferous ore by reducing it with the oxygen and hydrogen gas obtained, and thus producing either steel or pure malleable iron at will. To turn out two tons daily would, however, require the constant use of a 120-horse power engine.

SCIENTIFIC PROGRESS.

Artificial Gems.

Dr. Percy writes to the London *Times* with regard to Mr. Maclean's alleged discovery: "I agree with Mr. Maskelyne in thinking there is reason to expect that the diamond will some day be artificially produced. But, if so, possibly a very long period will be required to form a crystal of sufficient size and quality to be of any commercial value. Alumina, the substance of sapphire and ruby, has long ago been crystallized, yet to this day no artificial sapphire or ruby worth a farthing has appeared in the market. The balas ruby, or red spinel, was formed about forty years ago by Ebelmen, in small but distinct crystals, of which I have specimens in my collection; yet, so far as I am aware, the natural gem is alone known to jewelers. The conditions under which nature has crystallized carbon in the cubical system must be extraordinarily rare, seeing that a small room would probably suffice to contain all the diamonds that have hitherto been discovered. The possessors of diamonds have not at present any reason to fear that the value of their property will be lowered by the crystallized carbon of the chemical laboratory."

In reply to Mr. Story-Maskelyne's letter on this subject, referred to in last week's *Iron*, Mr. McTear says: "I have just seen Mr. Maskelyne's letter in the *Times*, and am surprised to learn first from it of the negative results Mr. Maskelyne has obtained, while an interview between us, fixed by him for Tuesday, 6th inst., is still pending. The statements in his letter do not prevent me from affirming in the most positive manner that I have been able to produce carbon in the diamond modification. I have been able on the only two occasions I have tried the experiment to burn the small translucent particles in oxygen gas, and I have been able with the greatest ease to scratch deeply both amethyst and topaz with them. As I do not despair of convincing Mr. Maskelyne himself of his being, to say the least of it, premature in his conclusions as to the problem of crystallization of carbon having been successfully solved, and as it has been accomplished by means very similar to those which in the concluding paragraph of his letter he suggests as being possible, I trust the scientific world will suspend their judgment until more ample evidence has been laid before them." At a recent meeting of the Glasgow Philosophical Society, St. John Vincent Day read a communication from Mr. Robert Baxter, of Dundee, regarding the production of artificial diamonds. Mr. Baxter began to experiment in 1876, but did not obtain successful results till April, 1877, when pure crystals of carbon were produced. The crystals then obtained were all lost through careless handling. Mr. Baxter endeavored to procure more, but for several months did not succeed. His crystals had been tested in a manner leaving no doubt about their genuineness. He had tried without success to produce large crystals, but saw no reason to prevent their ultimate production.

MAGNESIUM STEEL.—A half per cent. of magnesium changes coarse-grained into fine-grained steel and greatly improves the quality. The magnesium is introduced through an opening in the cover of the crucible, after inserting some small bits of charcoal, in order to remove the free oxygen. Without this precaution there would be danger of an explosion.—*Ber. der Chem. Gesell.*

A NEW PHOTO-PRINTING PROCESS.—M. Leon Vidal, in a letter to the *Photographic News*, says: Since I have had occasion to mention the name—a name never to be forgotten—of Poitevin, I should like to say a word on that gentleman's special process depending on the action of light on a layer of gelatine made insoluble by the following solution: Water, 100 cub. cents; iron perchloride, 3 grammes; tartaric acid, 1 gramme. Gelatine, with which this solution is incorporated, is insoluble, but ceases to be so in those parts where light is able to act by reducing to its natural state the iron compound. I have not myself been able to make experiments on the very interesting reaction here indicated; but as it has been published by a man whose assertion on such a point it would be impossible to doubt, I can at once see very important results that follow from it. I can foresee here a means of producing carbon papers for special purposes, these could be sensitized from the very first, for all that is requisite is to have insoluble pellicles of pigmented gelatine, stored in a dry and dark place, where they could be kept for a long time without detriment.

A NEW ELEMENT.—Tellef Dahl has found a new element, which he calls *norwegium* (Ng.), in a compound of arseniuret of nickel and nickel glance. It is white, somewhat malleable, of copper-like hardness, melting at a red heat, density 9.44. It dissolves with difficulty in hydrochloric acid or sulphuric acid, easily in nitric acid. The solution is blue, becoming green if diluted with water. Two specimens gave an atomic weight of 145.95. It is precipitated by caustic potash, ammonia and carbonate of soda; the green precipitate is soluble in all these reagents and gives blue solutions. Sulphureted hydrogen gives, even in very acid solutions, a brown precipitate insoluble in sulphuret of ammonia. Borax, in the oxidizing flame, gives a yellowish green globe, becoming blue in cooling. The blue color is shown in the reducing flame. It is easily reducible with carbonate of soda, or upon carbon.—*Comptes Rendus.*

THE DIFFUSION OF GASES.—Testing the diffusion of gases through collodion membrane may be done in the following manner: A piece of collodion balloon is fastened over the top of a funnel, which is then inverted and connected by a bent glass tube with a V-tube, into the bend of which is melted a piece of platinum wire. A little mercury is poured into the V-tube, and a second wire is arranged so as almost to touch the surface of the mercury. On connecting these wires with the two poles of a battery, no current will pass. The inverted funnel is now brought into a vessel of carbonic acid, when this gas slowly diffuses into the funnel through the collodion membrane. In five or ten minutes the pressure on the mercury will have raised it sufficiently to close the circuit, which can be made to ring an electric bell, or announce itself by heating a fine platinum wire.

ELECTROLYSIS IN SODA MANUFACTURE.—M. Merle, the manufacturer of the chemical works of Merle & Co., has erected electrical machines, which are employed to eliminate, by means of electrolysis, the whole of the iron and other metals, such as lead and arsenic. The separation of these metals is effected very rapidly, in large quantities, at a comparatively small cost. The soda crystals which are obtained from the concentration of the leys are very white, and well adapted to the bleaching of fabrics previous to drying. The manufacture of soda crystals and caustic soda, in the south of France, is very difficult, on account of the high temperature, which makes the mother liquors too rich in carbonate of soda.

URALIUM, A NEW METAL OF THE PLATINUM GROUP.—A. Guyard: As far back as 1869 the author discovered this metal in commercial platinum obtained from Russian ores. Next to silver it is the whitest metal known; its malleability is as great as that of the purest platinum, but its ductility is much greater, and it is almost as soft as lead. Its melting point lies near to that of platinum, and it is not volatile. Its specific gravity is 20.25, and its molecular volume, like those of osmium, platinum and palladium, is 6.25. Its atomic weight has been found to be 187.25. In its chemical properties it is difficult to distinguish from platinum.—*Chem. News.*

INTERESTING DISCOVERY.—Considerable excitement is said to have been caused in Lyons by a discovery which purports to give to flax all the qualities and appearance of silk. It has long been known that silk is soluble, not only in powerful acids, but also in soda and chloride of zinc, and it is said that these qualities are made use of in the new process. A company is being formed with a capital of $6,000,000 for the manufacture of the new textile.

HEAT OF THE ELECTRIC ARC.—Prof. Rosetti, of the University of Padua, has measured the temperatures of the electric arc and of the carbon points. He finds that with 80 Bunsen elements the negative pole measures 4,352° F., the positive pole 5,198° F., and the arc 6,332° F. These temperatures *decrease* with an *increase* in the number of elements employed.

ARTIFICIAL QUARTZ CRYSTALS.—MM. Friedel and Sarrazim have obtained quartz crystals by the action of hydrochloric acid upon gelatinous silica in closed vessels, at a temperature of 350° (662° F.)—*Soc. Chim. de Paris.*

Mining Share Market.

The inactivity that prevailed during the preceding week has extended into the present one. The sales have been light and with no prominent change in prices. There has been nothing to even ripple the surface, it has continued calm and quiet.

From all the mining districts the output of bullion is very encouraging; it is decidedly improving and the prospects are that the favorable state of the yield will continue for a long time to come.

The Solid Silver G. & S. M. Co. have declared a stock dividend of 10%, payable on and after February 15th. The Assembly Committee on Mines and Mining have agreed to report favorably on Gorley's bill regulating the sale of mining stock.

Novelties in a Novel Location.

Close under the Sierra Madre mountains, a rugged, precipitous range 13 miles east of Los Angeles, we were recently pleased to find a model machine shop, small in dimensions, but containing machinery remarkable for its perfection. It is owned by Mr. J. C. Davis and operated by Mr. J. K. Bigelow, late of San Francisco and formerly of the Springfield, Ill., watch factory. Here the models and working machinery are made for manufacturing Davis' now style of cigarettes. An upright tubular boiler and a two-horse power cugine supply the locomotion. A Pratt & Whitney lathe, a small planer, a hench lathe of hardened steel with numerous adjustable attachments for a variety of fine work and specialties, are among the equipments of this "gem of a workshop." It would be difficult to find more perfect machinery in any American metropolis than Mr. Bigelow completes with his own brain and hand work in this comparatively "out of the way" location. Mr. Davis calls his place Summer Hill—apropos to the fine climate. He owns 2,000 acres, principally mesa or gently sloping hench land. Its altitude places it in the warm or thermal helt, and notwithstanding the severe cold of the present winter, his ten-acre tract of tobacco, now partly in bloom, remains comparatively untouched by frost and steadily hut slowly continues growing. The land is ahundantly supplied with water for irrigating from the adjoining canyon. Oranges, lemons and other tropical fruits grow unsurpassed here; most temperate fruits and vegetables also flourish.

Of tobacco, Mr. Davis grows only the fine Havana in variety, always from imported seed. His plants last the year around, during which period he makes several cuttings. He has an experienced Cuban tobacco-raiser. Sets his plants in March in rows about four feet apart; plants 15 inches; gathers his principal crops in July and Septemher. Irrigates about once in ten days, during spring and summer months. Rates 600 to 700 pounds per acre a fair crop. He considers his soil as specially adapted to this culture, and that equally good land and facilities are limited in California. He has been seven years in bringing his cultivating and curing systems to their present perfection.

Mr. Davis' tobacco house is a well constructed building 32x132 feet in size, and is at present well occupied with the crops of the past year, as he has hut recently commenced selling it, and that in cigarettes only.

Machine Manufactured Cigarettes.

Mr. Davis is the only manufacturer, in America at least, of cigarettes wholly by machinery. The machine used is of his own invention, and is small enough to place in a lady's handbox. It is simple in its operation, but too difficult for us to describe intelligently without engravings. Over 1,000 cigarettes can be made per hour by this machine. When finished one end of each cigarette is inserted in a wooden socket, a perfect mouth-piece, which enables the smoker to obtain the full smoking flavor of the tobacco without any disagreeable or deleterious taste of the natural leaf in the mouth. For this reason the "consumer" will expectorate less, thus adding to comfort and health. We tested samples and can testify to the excellent flavor of Mr. Davis' pure Havana cigarettes. He manufactures none others. We anticipate that his "Cerrito del Yorano" will be the most popular brand of cigarettes in the United States, if not in all foreign countries. He intends soon to place them in the San Francisco market.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Zeile.—*Dispatch*, Jan. 31: Work on the open cut has been stopped, on account of breaking into an old tunnel that had been run from the shaft. The lead was struck and good rock found. A tunnel will be run in the same direction from the 100 level, which will strike the new lead at a lower depth.

Bluxom.—A blast of 5,000 pounds of powder was set off last Monday. The blast was exploded by an electric battery, throwing up about 40,000 cubic yards of dirt.

Commenced Work.—Work has been commenced by Morgan & Co. on the claim they recently purchased from D. Duty, near town, which they intend to thoroughly develop.

Bismarck.—Work was resumed last Monday by Vaughn & Co. This mine is located on Hunt's gulch, between Jackson and the Mokelumne river.

BUTTE.

Armstrong.—Oroville *Register:* The ledge has been tapped by two tunnels, one above the other, which are connected by a shaft. The upper tunnel extends into the hills about 200 ft and the lower one 250 ft, both showing a ledge three ft in thickness. The rock is easily handled and is delivered to the mill at a very small cost. The company has built a fine five-stamp mill, and supplied it with the best and latest improved machinery at a cost of $20,000, and the work of crushing has been going on four weeks. The rock averages $20 per ton.

CALAVERAS.

Banner Mine.—Calaveras *Chronicle*, Jan. 31: We have it from good authority that Mr. C. H. Livingston, of Columbia, who owned the well-known Banner mine, at Glencoe in this county, has sold that property to an Eastern company for $5,000.

INYO.

Taylor's Mines.—*Independent*, Jan. 24: Peter Taylor, of the new reduction works at Beveridge district, was in town yesterday, bringing in the handsomest lot of gold quartz specimens it has ever been our pleasure to look at from that auriferous region. He has nine locations, from one of which, the New Year, he, in less than a day, took from the ledge five tons of ore showing fine gold, which will yield from $500 to $1,000 per ton in gold. The ledge is two ft in width, carrying white quartz flecked with gold, and a stratum of iron oxide assaying high in fine gold. The specimens are undoubtedly rich, and it is evident that Beveridge district is an immense gold field. The arastra will start up soon, with 30 tons of ore on the dump and fine bodies of ore in sight in all the mines. Mr. Taylor expects within the next 60 days to have the stamps running.

Cosmopolitan.—There are 500 tons of ore above ground, estimated to work $100 or more. Some Mexicans, running arastras near there, have contracted to pack down and arastra 500 tons of ore.

MONO.

Standard Con.—Bodie *Free Press*, Jan. 29: The north drift, 385 level, is in from the main crosscut 642 ft. The ledge is four ft wide, of good milling ore. The upraise from this drift is 42 ft above the level, showing a ledge four and a half ft wide of good ore. The south drift from the main crosscut is in 315 ft. The ledge in the face is two ft wide of fine ore. The ledge in the upraise from this drift is three ft wide, and is looking very well. The east crosscut, 200 level, is in 187 ft. The rock in the crosscuts of the 700 level remains unchanged. The main shaft is down below the 700-ft station 64 ft. The north drift on the east ledge, 300 level, is in 227 ft, with a ledge in the face two ft wide, of good milling ore. The south drift from the west crosscut, 300 level, is in 142 ft, showing a ledge three ft wide, of very rich ore. The stopes throughout the mine are looking well. In the north drift, 385 level, the ledge is 20 ft wide, of high-grade ore. In the West Standard stopes the ledge is five ft wide, of rich ore. The ledge in the stopes, 550 level, is 10 ft wide, and is looking well.

Dudley.—The main crosscut, 500 level, is in 214 ft. On Friday last a heavy flow of water was struck, which has interfered with the progress of the work. The water is now held 12 ft below the station, with the pump running at 90 strokes per minute.

Belvidere.—Developments made since last report render it almost certain that the ledge in the 400-ft station is the same as that had in the shaft for 80 ft, between the 300 and 400 levels. The east crosscut has been stopped for the present, and north and south drifts are being pushed on the ledge. The north drift is in 30 ft and the south drift 25 ft from the shaft.

Bulwer Con.—The north drift on the Stonewall ledge is in 30 ft from the winze, showing a ledge 18 inches wide, of good ore. The south drift is in 22 ft. The ledge is two ft wide, and looks well. The north drift on the Ralston ledge is in 29 ft from the tunnel, with a ledge in the face of the drift three ft wide, of good ore. The south drift is in 24 ft. The ledge here is two and a half ft wide, and looks well. Stoping on the Ralston ledge was started during the past week, on the 380 level. The ledge is three and half ft wide, of very fine ore.

Jupiter.—The work of placing the new pumping machinery is progressing. The boilers are in position and the brick work nearly completed. The underground pump work on the 200, 250 and 400 levels is nearly finished.

Noonday.—They are crosscutting east and west on the 400 and 500 levels; both crosscuts are looking well. In the former, several veins of an encouraging character have been cut. Stoping in North Noonday from No. 2 winze, 300 level, and from Noonday vein, 200 level. They are taking out about 100 tons of ore per day.

Boston Con.—Work confined to the 200 level. The east crosscut is passing through a vein formation. Drifting south on the ore vein, which is about two ft wide, and assays $8 to $60.

Tioga.—Still sinking the main shaft, which has attained a depth of 738 ft. When the 800 level is reached, a station will be opened and crosscutting for the ledge commenced. Work of crosscutting from the Ralston winze, on the 620 level, continues. A vein four ft in width has been cut.

Summit.—The north drift, 530 level, has been extended 12 ft; total distance from the shaft, 01 ft. The ledge in the drift is three ft wide. The south drift is in 70 ft, showing a progress for the week of 10 ft. The ledge is two ft wide.

Double Standard.—The north drift from the east crosscut, 200 level, has been extended 13 ft; total length, 90 ft. The south drift, same level, is now in 91 ft.

South Bulwer.—The main shaft is down 482 ft. Winze No. 1 in the south drift, on the 350 level, is down 96 ft. The ledge in the bottom is four ft wide, of very good ore.

Ubo.—The west crosscut is in 101 ft. Formation is favorable. The east crosscut is in 188 ft. The face is in vein porphyry and quartz.

Blackhawk.—The shaft is down 600 ft. The bottom is in black porphyry, with seams of clay. The winze on the Liberty (west) ledge, sunk on an incline with and in the ledge, from the 220 level, is down 45 ft.

Quaker Bee.—The north drift, 400 level, is now in 35 ft. The vein is about seven ft wide, mixed with waste matter, but steadily improves as progress is made north.

South Noonday.—During the past week a whim has been erected over the shaft, and work will be commenced with it to-day. The shaft is down 136 ft, timbered to the bottom, double compartment. At 150 ft a station will be opened and a crosscut run to the Cummings ledge, which was cut in the shaft at a depth of 70 ft.

McClinton.—Bodie *News*, Jan. 29: South drift at new shaft has been extended a distance of 67 ft. West crosscut driven five ft to the west wall. East crosscut has been driven 12 ft, the face still in the ledge. This crosscut will be continued to the east wall, which will strike it at a point 77 ft from the north crosscut, giving them both walls, thus defining the course and direction of the ledge and enabling the company to know the exact distance necessary to be run to reach the ore body below. On the 500 level west crosscut in 207 ft. On the 675 level, north drift, in 74 ft, and the ledge is widening and looks well.

Sonora Con.—Progress during the week passed, eight ft. Crosscut from 100 level now in 83 ft. Rock in face of drift still continues hard.

Mammoth.—Mammoth City *Herald*, Jan. 21: Tunnel No. 3 has a total length of 701 ft. A new crosscut has been started and driven 21 ft. The rock is the same character of rotten quartz reported in our last. In No. 4, or lower tunnel, 20½ ft of rock has been removed, making the entire distance 954 ft.

NEVADA.

Vulcan.—Grass Valley *Union*, Jan. 30: So much water has been encountered in sinking the shaft of the Vulcan mine, on New York hill, that a horse whim cannot handle it and hoist the rock, and in consequence a boiler is being set up to run a steam pump. This work will be completed in a few days, when sinking will be resumed. The upper ledge has been cut through in the shaft, and shows a good quality of quartz carrying gold. The under ledge, which runs from the Ford & McDonald claim on the north (which produced very rich rock) is expected to be encountered in a few feet, and after the steam pump is started it will not be many daye before it is opened upon.

Mining Note.—Dutch Flat *Forum*, Jan. 29: We are informed upon reliable authority that the drift claim formerly owned by Pat. McCann, and situated near Remington hill, has rich pay dirt, averaging $8 per carload. This claim is south of and adjoining the claim owned by A. A. Ferguson and W. H. Hilhouse, of this place.

San Francisco.—Grass Valley *Union*, Jan. 31: Improvements are being made in ore sheds, contracts having been let for building 600 ft more, which workmen are now engaged in constructing. Upon its completion there will be 2,000 ft of ore sheds, capable of affording cover to 16,000 tons of ore, which is burned in piles of about 80 tons each. The company have now so many piles in process of burning that there is a regular and continuous supply of ore furnished for the leaching process, so that a fixed amount of cement copper can be turned out each month. The product of cement copper has been gradually increasing from month to month, until the intended maximum has nearly been reached, which is 45 tons per month. The product last month was 12 tons more than any month since the mine has been operating.

Shady Glen.—Dutch Flat *Forum*, Jan. 29: The last clean-up made not long since by A. Larson, at his claim, at Shady Glen, was better than any preceding one. One of the finest gold specimens we ever saw was left at this office. It is composed of hundreds of fine particles netted together having the appearance of frost-work.

Sargent & Jacobs.—The new shaft at Sargent & Jacobs' gravel claim, at Quaker hill, was connected with the tunnel on Wednesday the 21st inst.

Mining Note.—In the vicinity of Oleta (Fiddletown), a large amount of gold is being taken out of the gulches and ravines thereabouts in a quite unostentatious way by the miners.

PLACER.

Hidden Treasure.—*Herald*, Jan. 31: M. H. Power, Secretary and general manager of the Hidden Treasure Mining Co., Sunny South, called on us while in Auburn last Monday, and from him we learn that the mine is panning out well, and the prospects are encouraging. The main tunnel is in 1,050 ft, and a raise from the extreme point shows undiminished richness in the quality of the gravel. The mine is now giving a regular monthly dividend to the stockholders.

Rainbow.—The Rainbow, a rich drift claim, located in El Dorado canyon, above Sunny South, has been idle for some time for want of water to wash their gravel, but being supplied at present with an abundance, is in full operation and doing well.

Dam.—The Dam, another drift claim, in the same canyon, continues to give employment to its regular force, with satisfactory results.

Derby.—The Derby, owned by Willey, Shane, Lowell, Adams, Bardwell and others, and located about a mile above Sunny South, is being prospected with favorable indications.

Big Gun.—The Big Gun, a hydraulic claim, owned by the Van Emon Bros., at Michigan Bluff, and famed for its age and richness, is running steadily, and doing well.

Item.—Owing to the unusually cold weather, water has run light in the ditches, and the hydraulic mines on the divide, with few exceptions, have been running small heads.

Iowa Hill.—At Iowa Hill the mines have run but little this winter for want of water. There is a heavy fall of snow in the mountains, and the miners are in good spirits, as they know it has got to come some time, and they will get the good of it.

Highland Chief.—The Highland Chief, near the Sugar Pine mill, has been able to do but little recently for want of water to run their hoisting works.

Mountain Gate.—Work is progressing on the Mountain Gate mine at Damascus, and their prospects are improving.

Breece & Wheeler.—The gravel in the breasts is so rich that pieces of gold can be picked out with the fingers.

NEVADA.

WASHOE DISTRICT.

Belcher.—*Territorial Enterprise*, Feb. 3: The cable in the north incline having given out, work was suspended early in the week. It has been replaced by a new one and work resumed. Since then the north drift on the ore streak, on the 2760 level, has been advanced 17 ft, making its total length from the crosscut 47 ft. The face of this drift is still in very favorable-looking ground, with spots of ore through it. On the 3000 level work in the east and south drifts has been suspended for the purpose of cutting out and enlarging the station, as also to start a drift north to connect with the Crown Point. In addition to their own water the Belcher pump is taking the water of the Con. Imperial, the Yellow Jacket and the Overman.

Overman.—About 35 ft of the distance run this week has been through vein porphyry; the balance of the distance has been through quartz with seams of porphyry. Some of the quartz gives fair assays. At the Forman shaft work has been delayed somewhat by the extreme cold weather, ice having formed in the shaft to a depth of 500 ft.

Savage.—The incline has been sunk 14 ft; total distance on the slope, below the 2200 level, 185 ft. Bottom in hard rock, with but little water. They have placed new guides in north shaft for a distance of 512 ft. Drift from Combination shaft has been extended 67 ft; total length on drift, including station, 287 ft.

Bullion.—The incline winze has been sunk five ft, making the total depth on the slope 323 ft. They have completed a station on the 2350 level, and have started the north drift on this level. The formation at this point is vein porphyry with streaks of quartz.

Ophir.—On the 2500 level the main north drift has a total distance from the incline of 147 ft. It has passed through vein matter carrying quartz giving low assays. On the 2300 level the joint Mexican west crosscut has a total distance from the main drift of 344 ft, passing through soft vein porphyry. The north drift in the Hardy vein is in 32 ft, showing quartz in the face giving low assays. On the 2200 level the north drift in the Hardy vein is in 48 ft from the main drift. The south drift in the Hardy vein is in 48 ft from the main drift.

Union Con.—On the 2300 level the main south drift from the Union shaft has been connected with the joint Mexican winze down from the 2000 level. On the 2400 level the east drift from the ore stopes is now in 225 ft from the Union shaft, passing through vein matter carrying clay and quartz seams.

Sierra Nevada.—The north drift on the 2200 level has been advanced during the week 38 ft; total distance, 432 ft. The west crosscut on this level has been discontinued at a distance of 68 ft west of the main drift. At this point there was a heavy flow of water, and it became necessary to bulkhead the face of the crosscut. An east crosscut has been started 400 ft north of the shaft. On the 2300 level the north drift is in 230 ft. Crosscut No. 3, north on this level, has been stopped 48 ft west of the drift, having passed through some streaks of very good ore. Crosscut No. 2 is in 45 ft. This crosscut has passed through 11 ft of fair-milling ore. At 145 ft north of the incline they have commenced sinking a winze to the 2400 level.

Yellow Jacket.—The north drift is 50 ft past the north line. The north winze is 95 ft on the slope, but is retarded on account of a slight increase of water.

Mexican.—On the 2300 level the main north drift is 471 ft from the south line. The joint Ophir west crosscut on the southern boundary is in 344 ft from the main north drift. The connection between the joint Union Con. winze down from the 2000 level and the main south drift run by the Union Con. company from the Union shaft on the 2200 level has been made.

Gould & Curry.—The Gould & Curry and Best & Belcher joint shaft has been sunk and timbered 12 ft during the week; total depth, 896 ft.

Ward.—In consequence of a stratum of hard syenite rock encountered they have been enabled to sink and timber only 14 ft during the week; total depth, 2,004 ft. The shaft remains in this character of rock. Flow of water continues strong.

Hale & Norcross.—The south winze from the 2200 level is 127 ft deep. The bottom is in porphyry and quartz. The flow of water continues, and very hot. The north crosscut has a total length of 95 ft; face in hard porphyry.

BRISTOL DISTRICT.

Hillside.—Pioche *Record*, Jan. 24: Last Tuesday a large body of high-grade ore was encountered in the sinking of winze No. 1, from the west sixth level to the seventh. Its development will be looked forward to with a great deal of interest, for the winze is the deepest one from the sixth level, and the body of ore is the first tapped on that level south. The finest bar of silver bullion ever shipped from southeastern Nevada was run out of the Hillside refinery last Wednesday. It was 989 fine, and worth $1,897.10.

CONGO DISTRICT.

Mary Wilder.—Paradise *Reporter*, Jan. 24: This mine shipped about a ton of ore to Salt Lake, yesterday, for reduction. There is a considerable amount of apparently rich rock on the dump and in sight at the mine. Should the returns from this shipment justify it, other and larger shipments will be made soon.

PARADISE DISTRICT.

Paradise Mill.—Paradise *Reporter*, Jan. 24: The Paradise mill, which has been shut down since last Friday, in consequence of a broken shaft, was started up at noon Thursday, and has been running steadily ever since.

ARIZONA.

Stonewall Jackson.—Globe *Silver Belt*, Jan. 24: A specimen valued at $2,000 was shipped to San Francisco early in the week; since then a strike of surprising magnitude has been made, which, according to reports, beggars all others hitherto made, both in extent and general quality of the ore. The deep working in the Stonewall has settled the question in this section as regards the permanency of our mines.

Seminole.—One-half interest has been sold to John Winne, of Albany, N. Y.

Samenia.—Work has commenced on the main shaft. Good results are anticipated.

Happy Boy.—Prescott *Democrat*, Jan. 23: This mine is in Walker district, better known as Upper Lynx creek, eight miles southeast of Prescott. It is one mile distant from the Benjamin. The shaft is down 26 ft, and shows a body of two ft of very high-grade ore. Numerous assays have been made which range from $500 to $1,200. The ledge is in a talco slate formation.

Peck.—The wonderfully rich ore taken from this mine during the past four years has done more to attract the attention of the outside world to Arizona's matchless mines than any other discovery. The Peck has produced over half a million of the glittering treasure, and the work is nothing but surface scratching. The unfortunate litigation, which is part of the history of this property, has thus far prevented its proper development.

Item.—From Francis McMahon we learn, that on his recent prospecting tour he made the discovery of several valuable claims of silver and copper. Some of the ore which he exhibited assayed $500 in silver. The claims are situated about 20 miles southeast of Tiptop. Wm. Jennings has some very fine looking gold quartz, of which he says he discovered a ledge about one and a half miles west of the Davis mine. John Mars arrived in town from the Pinon ranch, and reports that they are steadily working on the Eureka copper mine, which is producing some good ore. An immense copper ledge has been discovered in the Agua Fria district, by McManus and Carpenter. The vein is more than six ft wide, and specimens of the ore are almost pure copper. George Clark, owner of the Continental mine, Turkey creek, has some fine specimens of silver ore from his claim. The Continental is one of the most valuable mines in the district, and Mr. Clark intends to thoroughly develop it.

Silver Chief.—Tucson *Record*, Jan. 24: One shaft of 125 ft shows metal going from $150 to $4,000, and a ledge 20 ft wide, with 13 ft of metal.

Independent.—Arizona *Miner*: This property is opening up very rich. They are working the ores by Mexican Baso process, and getting over $80 to the ton. The vein is six ft wide.

Model.—This is in Peeples Valley, two and a half miles from the stage road. Owing to the fact that the mine is located in the near vicinity to one of our finest agricultural districts, giving it the advantage of a near and easy market, is surrounded by timber, and in close proximity to water, having a fair vein of free milling ore, which assays over $100 per ton, it at once becomes a very desirable property.

Item.—West of the Santa Maria, in the Haqua-ha mountains, there is a mammoth copper deposit which will pay 90% by smelting process. From every direction we have the cheering news of rich copper discoveries.

Empire District.—Pima *Record*, Jan. 24: Mr. Harvey came in Thursday and brought some exceedingly rich ore from the Justice mine, assaying $2,190. This district is east of Davison's canyon, 45 miles southeast of Tucson, and comprises many good claims, among them the Total Wreck and Empire. On the Justice a tunnel of 63 ft and shaft of 38 ft has been run, showing a pay streak of solid metal, 14 inches in width. The Total Wreck has a tunnel 38 ft and drift 18 ft, and the Empire shaft 15 ft.

Washington Camp.—The mining outlook is better than ever. Good ore has been struck in the Ella No. 2 at a depth of 25 ft. A new opening north of the main shaft has been made on the Obio, exposing a body of rock, carbonate and galena, of marvelous extent and richness,

Continued on Page 92.

Disease-Germs.

An address delivered at the Anniversary Meeting of the San Francisco Medical Society, November, 1879, by J. H. Wythe, M. D., Professor of Histology and Microscopy in the Medical College of the Pacific.

In addressing this medical association, so largely representative of the scientific learning and culture of the most cosmopolitan city in the world, I am not vain enough to imagine that I can present any new theme, nor that I can better elaborate an old one than many of those who listen to me. I deem it an honor and a token of your confidence, to have been appointed your orator at this annual meeting, and can trust to your generosity to overlook whatever may seem immature or imperfect in my remarks.

In selecting a topic of general interest to the profession, rather than one which would tempt me to indulge in vague generalizations or eulogies respecting medical progress, I am following a custom of some of the leading scientific associations of Europe and America, and not unusual here—a custom both useful and appropriate.

The theme I propose is that of Disease-Germs, a subject so influential in etiology as to have quickened many fertile imaginations, from the days of Varro and Columella to the present, although it has also led to valuable practical results. If, in the light furnished by the recent advances of biology, I can dissever the romantic and imaginative from the true, so as to indicate the real importance of disease-germs among the *materies morbi*, I shall have accomplished much.

Every agency of nature outside of the bodily organism, and every activity of body and of mind within the living structure, is capable of becoming a cause of disease, as soon as it disturbs the normal current of life, so that the number of causes is practically unlimited. Of all the causes of disease, the most difficult to isolate and investigate are those which produce what are known as miasmatic and contagious, or infectious, diseases—diseases which may be diffused through the air or water, and those which spread from one person to another.

Formerly infectious diseases were regarded as products of gaseous chemical action—so-called fermentation—or zymotic diseases; but more recently they have been considered to be each the result of a virus, in all probability specific; or a special poisonous substance has been imagined for each disease. The discoveries of the last few years have tended still further to isolate the causes of this class of diseases, and the theory of *contagium vivum* has found very general acceptance. In other words, the belief is now very general that the causes of contagious affections, and perhaps also of miasmatic diseases, are living, or organic, causes, so that these derangements are not merely the physical or chemical result of the action of inorganic matter. From this view it is but a step to the germ theory of disease.

Under the general title of disease-germ, two distinct theories claim consideration: 1. The theory of vegetable parasites in the blood, generally fungi, and of this class most commonly the various species of *Bacteria*. This has been very elaborately worked out by the German pathologists, and has been favorably regarded in other countries since the publication of the observations of Pasteur, Salishury and others. 2. The germ theory of Dr. Lionel S. Beale, who considers that "the particles concerned in the propagation of contagious diseases are allied in constitution to the living matter, or bioplasm, of the organism," and "derived by uninterrupted descent from the bioplasm, or living matter, of an organism, which at an antecedent period may have been perfectly healthy."

The definition of a germ given by Dr. Beale is identical with what modern biology terms a cell, or the elementary unit of living beings. It is simply a piece of bioplasm, "a particle of living matter, which has been detached from already existing living matter." "The living particle which sprouts from a cell of the adult plant or organism, and is then detached, may be called a germ, as well as the living particle formed in the ovum, or the living matter in the ovary, from which the new being is evolved." It is evident that this meaning to which the term "germ" is restricted is a special meaning, and, so far as it implies reproduction, is limited to the multiplication of similar cells, and not of individuals, as in the case of the ovum. The various masses of bioplasm into which the ovum of man or of the higher animals subdivides, are exact counterparts of each other, so far as external appearance and chemical composition are concerned, but they differ greatly in power. Some produce glands; some, muscle; others, nerve, bone, vessels, etc. The powers of these bioplasts, once lost, can never be regained, although they may continue to live and be nourished, and multiply even more actively than before. Indeed, observation shows that degradation in power is generally associated with increased rate of growth and remarkable vitality, as in the rapid growth of embryonic cells in new formations, etc.

"Abnormal cells cannot be regarded as parasites upon healthy cells, although many forms of abnormal bioplasm, like pus, cancer, etc., may be transferred from animals to man, or vice versa, and grow and multiply."

"If such bodies as mucous corpuscles, pus corpuscles, cancer cells, tubercle corpuscles and disease germs generally, be termed parasites, the nails, or hairs, or glands, or limbs might with equal propriety be regarded as of this nature."

The following *resume* of Dr. Beale's theory is from his work entitled, "Disease-Germs; Their Nature and Origin," a work which will well repay careful perusal. The most recent biological researches have almost uniformly tended to confirm the statements made in it.

"The minute contagious bioplast is less than the 100,000th of an inch in diameter, and often so very clear and structureless as to be scarcely distinguishable from the fluid in which it is suspended. Such a minute particle may readily be transferred from the affected organism to an apparently sound organism. It may be carried a considerable distance from its source without losing its marvelous power of causing in the organism invaded a series of changes resembling, and often in very minute particulars, the phenomena which have occurred in the organism from which it was derived.

"And it is established that there exist different kinds of contagious living bioplasm, each capable of occasioning specific phenomena which distinguish it. The poison of small-pox will produce small-pox, not typhus fever, or measles, etc., nor will any of these produce small-pox. Without, therefore, pretending to identify the actual particles of the living bioplasm of every contagious disease, or to be able to distinguish it positively from other forms of bioplasm, healthy and morbid, present in the fluids, on the different free surfaces, and in the tissues, in such vast numbers. I think the facts and arguments I have advanced prove: first, that the contagious virus is living and growing matter; secondly, that the particles are not directly descended from any form of germinal matter or bioplasm of the organism of the infected animal, but they have resulted from the multiplication of particles introduced from without; thirdly, that it is capable of growing and multiplying in the blood; fourthly, that the particles are so minute that they readily pass through the walls of the capillaries, and multiply freely in the intestines, between the tissue elements, or epithelial cells; and lastly, that these particles are capable of living under many different conditions—that they live and grow at the expense of various tissue elements, and retain their vitality, although the germinal matter of the normal textures, after growing and multiplying to a great extent, has ceased to exist."

These views Dr. Beale elaborates with great force and plausibility. He admits that myriads of vegetable organisms, microscopic fungi and algæ of different kinds, and their germs, may enter the human body, and are actually seen in the fluids and tissues of the higher animals during life, but he claims that all attempts to demonstrate constant species of bacteria, representing different contagious diseases, have completely failed; that the beneficial action of Mr. Lister's antiseptic treatment of wounds is traceable to the influence of carbolic acid upon the growth of bioplasm, and that the virulence of the poison in cases of dissection-wounds is greatest before putrefaction and the development of bacteria—the real virus losing its power soon after bacteria appear. He states that those diseases which are known to depend upon the growth and development of vegetable organisms are local affections, not involving the blood, and that very few morbid conditions depend upon fungi, whose germs multiply in textures already deteriorated, rather than in tissues previously healthy.

On the other hand, recent biology has shown that the animal and vegetable bioplasm have similar endowments as to nutrition, growth and reproduction. In the vegetable, or fungus cell, the bioplasm is imprisoned in a cell-wall of cellulose, while in the animal it may be either free or encased in formed material of different kinds. As to the fungi, it has been quite satisfactorily shown that they are the exciting and essential cause of both fermentation and putrefaction. They form a very extensive class of primitive organisms, which have so many peculiarities that some have been led to regard them as different from both animals and vegetables. They look like vegetables, but feed as animals. They have no chlorophyll, as the green vegetables have, and which enables them to break up carbonic acid. Light is not essential to their activity, as it is to that of green vegetables, and they are incapable of assimilating inorganic food, but require organic substances for their support. The bioplasm of some kinds of fungi has amœboid movements, like other primitive forms of life, yet their principal office seems to be to break down and restore effete organic material to the inorganic world. The excessively minute and almost vapor-like sporules of fungi float about in the atmosphere in countless numbers, only waiting for a fitting soil in which to grow. As long as there is no refuse matter to be removed these scavengers are unemployed, but the smallest quantity of decaying animal or vegetable matter left exposed, becomes covered with spores, which develop with astonishing rapidity. A scanty number of spores, only to be detected by careful research, will in a few days, and sometimes in a single night, give birth to myriads, to repress or remove the nuisances referred to. When the offal diminishes, fewer of the spores find soil on which to germinate, and when all is consumed the active legions return to their latent or undeveloped state. Like Milton's spirits

> "So thick the aery crowd
> Swarmed and were straitened, till the signal given,
> Behold a wonder; they but now who seemed
> In bigness to surpass earth's giant sons,
> Now less than smallest dwarfs."

Many of the most simple forms of fungi have been shown by recent investigations to be imperfectly developed states of other species. The *Torula cerevisiæ*, or yeast plant, whose growth is the cause of fermentation in solutions of sugar, and various forms of *Bacteria* which cause putrefaction in animal substances, appear to be but varieties, or stages in the development of some of the molds. On account of this polymorphism, or assumption of different forms, in the life history of these organisms, their study is very difficult. Those genera and species which are of most interest in pathology and etiology, may be however provisionally classified as follows, after Wagner: *(Manual of Gen. Path.)*

I. Dust, or Germ-Fungi *(Coniomycetes)*. These consist of single, or loosely connected spores, which sometimes develop a mycelium, or filament, from which other spores are formed by constriction.

Here belong the "rust" of grain *(Uredo)*, and the yeast-fungi (*Torula*).

II. Filamentous Fungi (*Hyphomycetes*). In these the mycelium consists of lengthened tubes, often branching in elegant figures, and bearing spores.

The "molds" belonging to this order, as the *Penicillium*, or common fruit mold; *Aspergillus*, club-mold; and *Mucor*, with bladder-like fruit on the mycelium. Here also are placed the fungi found in various diseased states, as that of the muscardine in silk-worms (*Botrytis bassiana*), the potato-disease (*Fasisporium solani*), the grape-disease (*Oidium Tuckeri*), and the fungi of diseases of the skin and mucous membranes, as the *Tricophyton tonsurans*, found in ringworm, mentagra, etc. *Achorion Schonleinii*, or favus-fungus, *Microsporon Audonii*, *Microsporon furfur* and *Oidium albicans*, or thrush-fungus.

III. Cleft-fungi (*Schizomycetes*). Here are placed the various forms of bacteria:

1st group, Globular bacteria.

1st genus, *Micrococcus*. These are globules or oval cells, sometimes united into bead-like filaments, or rounded masses. They are sometimes seen in ammoniacal urine, and are regarded by many as "ferments of contagion," and the cause of diphtheria, pyemia, etc.

2nd group, Rod-like bacteria.

2nd genus, *Bacterium*.

They are of short cylindric form, and have spontaneous motion. *B. termo* is the ferment or cause of putrefaction.

3d group, Filamentous bacteria. Elongated cylinders, increasing by transverse division.

3. Genus, *Bacillus:* Straight filaments. *B. anthracis* is found in gangrene of the spleen.

4. Genus, *Vibrio*. Wavy filaments, seen generally in putrifying solutions.

4th group, Screw-bacteria.

5. Genus, *Spirochæta*. *S. plicatilis* is found in tartar from the teeth.

6. Genus, *Spirillum*. Spiral shorter than the last. In this group also may be placed the *Leptothrix buccalis;* long, slender filaments from the mouth, etc.

The principal argument in favor of considering fungi as the disease-germs of contagious and miasmatic disorders, are thus given by Prof. Liebermeister in Ziemssen's Cyclopedia. "In this connection there are facts of considerable importance, which have been furnished by recent investigations into the nature of many contagious diseases in animals and plants. The contagious diseases of the silk-worm, which have been a source of so much danger to the silk-worm culture, have been proved to be parasitic, and the history of the parasite has been followed thoroughly. In flies and many other insects, we have known similar epidemics of a parasitic nature to have taken place.

"The epidemic and contagious diseases of the higher classes of cultivated plants, such as the potato disease, the grapevine disease, the ergot of grain, and others, all are derived from fungus-growth. The question, too, on which for a long time opinions were divided, as to whether the fungus were the cause, or only the consequence of the disease, has been answered by the botanists with unanimity. Where the development of the fungus had been thoroughly examined, they reported that it was the sole and sufficient cause of the disease. It is clearly evident, too, that the further the progress of investigation advances in human pathology, and the more frequently low organisms are shown in diseases, the more prominently will this question urge an answer."

Prof. Wagner, of Leipzig (*Gen. Pathology*, p. 108), while acknowledging his belief that many important affections are caused by fungi, confesses that the subject is yet involved in much obscurity and doubt. He says: "No two observers have, concerning the same disease, reached the same results; the specific fungus of one is disavowed by another, etc. But in spite of all that, much is yet to be expected from the further cultivation of this field, with respect to the etiology, etc., of many diseases."

The fact that "filtration of putrid fluid through porous porcelain under pressure deprives it simultaneously of its offensive smell, poisonous action, and power of generating bacteria," proves that the infectious quality does not reside in the fluid, but in what is contained in the fluid—*Essay on Disease-Germs, by B. A. Watson, M. D.* Now in the fluid of the small-pox vesicle, in the blood and secretions of animals suffering from the cattle-plague, and in the products of other contagious diseases, Dr. Beale has found multitudes of rapidly growing bioplasts, and his statements have been fully confirmed by subsequent research. Dr. Salisbury and others find bacteria and other fungi in malarial and contagious affections. Each considers he has found the true *contagium vivum*. But may not both be true? The fungi, as well as all living things, spring from bioplasm, and may have their share in producing disease as well as the degraded bioplasm of the human tissues. The latter must be a frequent cause of disease. There can be no doubt respecting the propagation of purulent opthalmia or gonorrhea by the germs, or leucocytes, which are transferred from one mucous membrane to another. "A single epithelial cell may carry multitudes of active particles of syphilitic poison, one of which introduced into the blood or lymph of a healthy person would probably grow and multiply, and give rise to pathological changes characteristic of, and quite peculiar to this particular poison." When we remember that these particles are excessively small, although alive; that they may continue to grow outside of the parent organism, and acquire by the abnormal conditions of their growth new and virulent properties; that when dried, and in a state of dormant vitality, they are sufficiently light to be carried by air currents to great distances; and that on contact with warmth and moisture, and especially with secretions similar to those whence they originate, they will at once begin to germinate and multiply; all the reasonable conditions of *contagium vivum* are fully met. On the other hand, the known properties possessed by fungi, of exciting fermentation and putrefaction, forbid us to suppose that their presence in considerable numbers in animal fluids is of no moment. Secondary infections, if not primary contagions, must be regarded as the probable result of the presence of these organisms.

The question of the spontaneous generation of germs is largely disposed of by either of the theories referred to. Besides, the careful experiments of Pasteur have fully shown that air filtered from its germs by cotton-wool may be admitted to fluids in which all germs have been destroyed, and no living organisms will appear in them. The experiments of Prof. Tyndall with air made so pure that a brilliant ray of light shows no suspended germs in it, and in which no infusorial organisms occur, although abundant in common air, establish the same theory. Messrs. Dallinger and Drysdale have also shown that some germs will resist a heat of 300° F., which accounts for infusoria in some boiled infusions. So that we may regard it as a settled axiom of modern science that every living being originates from a previously living being.

On either the bioplasmic or the fungoid theory of disease-germs, the practical utility of Lister's antiseptic treatment in surgical operations finds a rational explanation. The recent accounts published by Dr. Keith, of Edinburgh, of the application of this treatment to ovariotomy, prove how great an improvement has been made in this direction. Increased skill, and special care in operating, have doubtless much to do with the result, yet the fact remains that graver cases may be successfully treated with the use of carbolic acid spray and carbolized dressings, than a prudent surgeon would have undertaken at all otherwise.

Dr. Beale's bioplasmic theory illustrates the good effects of the sulphites, and especially of the sodium sulpho-carbolate in zymotic diseases. I have used the latter in 20 gr. doses three times a day in some cases of cancer, and have thought it had some influence in arresting the growth of embryonic abnormal bioplasm. In some cases of diphtheria and scarlatina maligna it was of undoubted benefit. It deserves a more extended and careful trial.

I need not do more than remind you, in closing this brief review of the subject, of the importance of obtaining accurate information respecting it, by careful observation; to stamp out pyemia, hospital gangrene, erysipelas, and similar affections by antiseptic treatment, and to so learn the course of production and propagation of disease-germs as to be able to adopt a course of public hygiene which shall neutralize the risk of communities being decimated by pestilent scourges, like cholera, or typhoid and malarial fevers. Such are the results which may be expected by the attainment of positive truth upon this subject. So desirable a consummation is worth years of pains-taking study and experimentation, and the physician who succeeds in this direction will have earned the gratitude of succeeding ages.

Cost of Mining in Utah.—The following are the rates of mining cost by day or contract. For working the mines dead work, pumping, handling ores, etc., it is in different districts about as follows:

District.	Mines.	Price per ton.
Park	Ontario	$6.50
Big Cottonwood	Flagstaff	9.00
Bingham	Old Telegraph	4.00 to 5.
Silver Reef	Stormont, Leeds	6.00 to 7.
Frisco	Horn Silver	8.00

Generally it ranges from $4 to $10 per ton. Miners' wages run from $2.50 to $3.50. A small number of Mormons work in the mines. The Church discourages it. Laborers, on the surface, at mills, furnaces, etc., receive from $1.50 to $1.75. In the Silver Reef or metalliferous sandstone region wages range 25% higher than elsewhere. Wood costs from $4 to $6 per cord. Coal along the Union Pacific and Utah Southern will cost from $7 to $8 per ton; elsewhere it ranges as high as $12 to $15 per ton. These are the figures in the mining camps.—*Silver Reef Miner.*

The number of Scotch furnaces in blast at the close of December was 100, or eight more than at the corresponding period last year. Each furnace produces about 195 tons per week.

Relocating and Jumping.

What Constitutes $100 Worth of Labor and Improvements?

Some twenty odd mining claims have been either jumped or relocated within ten days past. Several claims held by a person not a citizen were relocated, and a number have been jumped or relocated, on the ground that sufficient work had not been done to comply with the law in such case made and provided. There seems to be a difference of opinion as to what constitutes the $100 expenditure required by the United States laws. Some persons in the district have annually expended $80 for labor, and added $20 for cost of powder, fuse, tools, etc., making the total $100, and upon application to the Recorder received a certificate that the lawful amount of labor had been performed. The parties who have relocated a number of such claims hold that $100 worth of actual labor must be performed each year, and that the law has not been complied with. The point is one which may cause much litigation, if it is not better defined by law or settled by decision. The literal reading of the statute is as follows: "On each claim located after the tenth day of May, eighteen hundred and seventy-two, and until a patent has been issued therefor, not less than one hundred dollars' worth of labor shall be performed or improvements made during each year." The record of the affidavit of the claimant "that at least $100 worth of labor or improvements" have been performed or made is *prima facie* evidence of the performance of such labor, but so far as we know the question as to whether the money expended for powder, tools, etc., can be counted as part of the $100 worth of "labor or improvements" has never been decided by the Commissioner of the General Land Office. But the statute says "the miners of each mining district may make regulations not in conflict with the laws of the United States, or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording, and amount of work necessary to hold possession of a mining claim," and it is held by some persons that the last clause of the quotation gives the miners the right by local laws or custom, to say what shall constitute $100 worth of "labor or improvements;" for instance, that sinking a shaft or running a tunnel a specified number of feet should be worth $100. The custom in this district has been to count the cost of materials used in making permanent improvements on claims, such as sinking shaft or driving tunnel or drift, and claimants believe this will hold good in the courts. However, until the law is made more definite, or the matter settled by decision, perhaps, it would be well for parties holding valuable claims to perform fully $100 worth of labor, without regard to the cost of the necessary tools and materials. Expensive litigation, with possible loss of good bonanzas, may thus be avoided.—*Esmeralda Herald.*

Petroleum Product of 1879.

From *Stowell's Petroleum Reporter* we gather the following facts, which show the enormous proportions which this branch of industry has attained. It is not in the great amount of crude oil that is produced and the wealth which it adds to our nation alone, that its advantages are manifested; but they are still further evinced in the great field of labor which they have created and are keeping in activity, giving work directly and indirectly to hundreds of thousands of workers. We give the annexed quotation from the *Reporter* as a concise summary of the production of 1879:

The petroleum business during the year just closed has been marked by many results never before attained. The enormous production of crude (nearly 20,000,000 barrels) exceeded the production of any previous year by about 5,000,000 barrels. The average price of crude at the wells for the year was 94⅜ cents per barrel, being 39§ less than for the year 1874, which has been considered heretofore the cheap oil year. The number of wells drilled during the year was 3,038, which number was not greatly in excess of former years, only about 6¾% of the wells completed proved to be dry or worthless against 11½% of dry holes developed in 1878. The shipments out of the producing regions have been larger than in any previous year, amounting to nearly 16,000,000 barrels, which exceeded the shipments of 1878 nearly two and a quarter million barrels.

We regret to learn that there is a steady decline in the production in oil fields of Pennsylvania, on which point the *Reporter* states:

The maximum production of crude petroleum in the Pennsylvania oil fields was reached in August, 1879, since that time the production has undoubtedly been steadily on the decline and from present indications we may look for a continued decline, slowly but surely, until some new and now unknown field shall be found which shall yield the precious fluid bountifully.

The actual number of barrels—equivalent to 42 gallons each—that were produced in 1879 was 16,261,825, making a daily average of 53,523. The total number of barrels, equal to 40 gallons each, exported from the United States in 1879 was 10,441,213; equal to 28,606 barrels each day.

The average prices per gallon in barrels during the year were for crude, 7.10 cents; for refined, 8.08 cents; and for naptha, 6.54 cents.

Useful Information.

Paper Hanging.

Paper-hanging is quite a modern invention, after all; that is, in its Western use. In the East wall-papers had been known from time immemorial; but it was only toward the end of the seventeenth century that they were brought from China, imported into England and Holland along with a multitude of other indiennes and chinoiseries. France took hold of the idea and perfected it, and has hitherto produced the best, while Germany and Belgium have given the cheapest papers; but England has lately come to rival France. There is now a vast variety to choose from everywhere; mounting from the rough kitchen fourpenny paper that, put on wrong side out, when its pattern is but slightly stamped, presents a uniform gray surface like something a great deal more expensive, and where the pattern is heavily stamped, presents a damascened gray surface, to those elaborate in art and material, whose use in a single room requires an expenditure of a small fortune.

There are the common satin-faced ones, the gilded, silvered and bronzed grounds, embossed gilt and mica, imitation of silks and tapestries, cretonnes and chintzes, raised and stamped velvets; there are some like delicate muslins embroidered in chain stitch and lined with color, at six dollars a roll and upwards; others like the dark, old, embossed Spanish leathers buttoned to the wall, from nine to twelve dollars a roll, according to present prices; there are the thick, Japanese papers, where the black ground riots in fantastic assemblage of all rich colors, where a gold ground carries birds and butterflies and fans in charming profusion, and those of lighter, less marked and less agreeable characteristics, at about the same price as the leather papers; others yet more expensive, thick and heavy, a finely-glazed porcelain-like representation of tiles of all sorts, for those who will have them in imitation; and in addition there are the frescoed papers, and those for ceilings, for dados and for friezes. It would be hard if out of such a variety one could not get up rooms that would be satisfying to the most demanding sense of the beautiful.

Cork and its Value.

The constantly increasing demand for cork for bottling and other purposes, together with the fact that the cultivation of the tree is sadly neglected, threatens to cause a serious dearth of the article. Yet no other substance has been discovered that will serve as a substitute for cork in many of the uses to which it is applied. Cork is worth 11 times what it was a century ago, and its market value is continually increasing. The American Commissioner of Agriculture has satisfied himself that the cork tree can be successfully cultivated in various parts of the United States, and in his report for 1878, just issued, recommends that the Government offer premiums to those who, within a reasonable specified time, shall have obtained the best results in cork culture. In Sicily, Sardinia and the kingdom of Italy, great plantations of cork trees have been destroyed to obtain the tannin from the bark. After having been stripped of their bark, the trees were burned, in order that the carbonate of soda might be extracted from their ashes. In 1822 the French government began to nurture this important interest, and France now has about 500,000 acres of cork plantations in Algeria. The tree grows as high as 65 feet, with a diameter of from 3 to 5 feet, and will live and yield cork from 150 to 200 years. In a dry, sandy, siliceous soil, at an altitude of from 1,600 to 3,200 feet, and not further north than the 45° of latitude, cork plantations will flourish. The tree does not, however, yield valuable cork until it is towards 15 years old.

To Dye Straw.

Magenta Red.—The first operation for dyeing this or any other color on straw is to steep the latter in a bath acidulated with sulphuric acid for 12 hours. For magenta, take an acid bath of 4° to 5° Be. The straw after washing is immersed for 12 hours in a bath kept at 30° to 40° C., containing the necessary amount of dye. Now wash well and dry. Other aniline colors do not dye straw with the same facility.

Maroon, with Logwood.—Clean the straw by boiling with a solution of carbonate of soda, then steep in a bath of logwood for two hours. To give a bluish tint, add some bluestone to the bath; if too much of the latter is used the straw will have a greenish hue. This is a loose color, only employed on account of its cheapness.

Coffee and Chocolate Stains.—If the coffee or chocolate contains milk, the stains produced are more pronounced than if prepared with water only, but they are also more easily removed. To remove them, the stains are washed with a mixture of yolk of egg in tepid water. If with this treatment they still remain, add a little spirit to the mixture, and rub with a hard brush.

Blue Linings for Hats.—In producing these the cloth is not dyed, but the thickened color is applied to it in the following manner: Prepare the color with 22 gallons of water, 30 pounds starch, 2 pounds tallow, 44 pounds ultra-marine blue; mix, boil, pass through sieve; print on the roller first on one side, then on the other, and dry on the cylinder.

Skeleton Leaves.—The following method has been communicated to the Botanical Society of Edinburg, by Dr. G. Dickson: A solution of caustic soda is made by dissolving three ounces of washing soda in two pints of boiling water, and adding one and a half ounces of quick-lime previously slacked; boil for ten minutes, decant the pure solution and bring it to the boil. During ebullition, add the leaves, boil briskly for some time, say an hour, occasionally adding hot water to supply the place of that lost by evaporation. Take out a leaf, put it into a vessel of water, and rub it between the fingers under the water. If the epidermis and parenchyma separate easily, the rest of the leaves may be removed from the solution and treated in the same way; but if not, then the boiling must be continued for some time longer. To bleach the skeletons, mix about a drachm of chlorido of lime with a pint of water, adding a sufficient acetic acid to liberate the chlorine. Steep the leaves in this until they are whitened (about ten minutes), taking care not to let them stay in too long; otherwise they are apt to become brittle. Put them into clean water, and float them out on pieces of paper. Lastly, remove them from the paper before they are quite dry, and place them in a hook or botanical press.

To Remove Nitrate of Silver Stains.—Dr. Kraetzer, of Leipsic, proposes, as a substitute for potassium cyanide in the removal of stains made by lunar caustic or silver nitrate, the following mixture: 10 grammes ammoninm chloride, 10 grammes corrosive sublimate, dissolved in 100 grammes of distilled water, and preserved in a glass-stoppered bottle. He says that with this solution the black stains may be removed from linen, woolen and cotton goods perfectly, without injury to the goods. It will also remove stains on the skin, but, although less poisonous than the cyanide, it must not be forgotten that it is a corrosive poison. For the skin we prefer to apply tincture of iodine, or a solution of iodine in iodide of potassium, followed by strong aqua ammonia; if slower, it is safer both to use and to keep in the house.

A New Boot Sole.—A Chicago boot manufacturer, Mr. Goodrich, has introduced what he is pleased to call an indestructible sole, in which nickel-plated steel rivets are embedded in the leather. These rivets are forced through perforations from the inside of the sole to its outer surface, and being less in length than the thickness of the leather, the head is securely embedded, and does not drop out as the sole becomes worn. Owing to the nickel-plating, it is claimed there is an entire absence of rust.

To Keep Belts Soft.—To keep belts soft and pliable, but little care is generally needed, but a little attention on this point would be well worth the while of many mill-owners. When a belt is dry and husky, but still pliable, a little blood-warm tallow, dried in by the fire or the heat of the sun, is all that is needed. When hard and dry, apply neat's-foot oil mixed with a small quantity of resin.

Iron Protected by Gum.—Sheet iron covered with gum of the euphorbiaceæ, common and luxuriant in tropical climates, was immersed in Chatham, England, dockyard, where everything rapidly becomes foul, and when taken out was found quite clean. The gum is intensely bitter and poisonous; hence marine animals avoid it.

A new kind of crockery, designed to fill the place of earthenware to some extent, has recently been introduced. It consists of cotton pulp, or felt, glazed with a composition into which dissolved glass largely enters. It is a durable, elastic material, possessing neither the great weight nor brittleness of earthenware; but it has yet to undergo the test of general use.

Good Health.

Bee Stings.

Nearly twenty years ago I lived in western Ohio. Our family consisted of my wife and myself, a little girl about three years old, and a little boy, a babe. One day my wife started on a visit on horseback, intending to return in the evening. I helped her on the horse, and went probably about thirty rods distance with her to let down the fence for her to pass through. During the time we left the children in the house, thinking they would not be likely to receive harm till I came back; but, to my great surprise, on returning to the house I found that the little girl had made her way to the bee-hives, and, I suppose, had thrust out one of her arms into a hive, as it stood up some distance from the ground, and in this way had stirred up the bees. When I took her into the house she was suffering extremely from the great number of stings which she had received. I took her upon my knee, and counted the number of stingers as I pulled them out from her face, arms and neck—I found 33—and afterwards discovered that there were as many more in her hair. Of course this looked to me like a very serious injury—enough to cause her death, if I could not adopt some mode of treatment that would be very effective. I had not been in the habit of using medicine in my family in a long time, but depended entirely upon water. After pulling out the stingers, I stripped the child, filled a tub half full of water, right cold from the well, and placed her in it for about a minute; then took her out and wrapped her in a sheet, and put her in the cradle. I repeated this process, bathing her about three times, ten minutes apart, and had the satisfaction of seeing it alleviate her suffering. After I had bathed her three times and wrapped her up warmly in the sheet, she dropped to sleep and did not wake up for about 20 minutes. Then the fever and pain woke her up, and I bathed her again. After two more baths she slept soundly, and on waking seemed to be nearly recovered. By the time her mother came home that evening, she was able to be around, with scarcely any marks of the stings upon her person. I do not believe that any other than water treatment would have brought about such a good result in so short a time. —*Ex.*

A Remedy Making Spectacles Unnecessary.—Dr. W. Cheatham writes to the Louisville *Medical News*, that he has found that the use of the sulphate of eserin makes it unnecessary to use spectacles in case their use is called for by a flattening of the cornea from old age—a very common ailment, called presbyopia. He states that this drug possesses the property of acting especially on the ciliary muscle, and contracting it, which contraction increases the convexity of the cornea. He recommends dissolving one gram of the sulphate of eserin in one ounce of water, and putting one drop in each eye at bed-time. It produces at first the opposite defect—a too great convexity of the cornea, which is called myopia, or near-sightedness, which, however, soon passes away. He thinks the use of this remedy perfectly safe, and also adapted to cases of glaucoma and other inflammations of the eye, in cases of weakness resulting from overwork, general debility, diphtheria, etc. He says that notwithstanding the use of spectacles in case of presbyopia gives comfort to the eyesight, there is also, however, always some trouble connected with them, which patients are often anxious to dispense with, and thinks they should be humored in this respect. We are of this opinion also, but advise caution in using this new remedy, because, as the effects are only temporary, a continuous use is of course intended, and experience has not yet shown what secondary effects may result from often repeated applications.

Benefits of Exercise.—In addition to the physical benefits derived from athletic exercise, it has a moral value; it affords a diversion and a vent to those animal energies which otherwise are sure to explode in debauch and all kinds of vicious excesses. The sympathetic thrill by which the mind accompanies a daring gymnastic feat, and the enthusiasm of athletic contests form the most salutary and, perhaps, the only normal gratification of that love of excitement which is either the legitimate manifestation of a healthy instinct, or else a wholly irremediable disease of our nature. The soul needs emotion as the body needs exercise—a fact we do not, as a people, realize. In times of scarcity the paupers of China and Siam silence the clamors of their hungry children by dosing them with opium; and for analogous reasons millions of our fellow citizens seek relief in alcohol.

Warm Clothing.—If you are apt to feel chilly dress warmly at home. A wadded coat will enable the chilly man to sit and work anywhere in doors, and so will an extra suit of thin flannel worn during the whole of the active day. Just let anyone who doubts what we say try the very simple expedient, when the chillness becomes unbearable, of putting on his dressing-gown over his ordinary clothing, and in five minutes he will be perfectly comfortable and ready for work, while he will not suffer as he fancies he will, when he goes out of doors. The popular notion upon that subject is a mere delusion. You are not strengthened for outdoor work by shivering indoors, but rather weakened; habitual warmth, if not too great, being one of the best preservatives of constitutional strength. Always try to remain moderately and healthfully warm.

Benzoate of Soda for Diphtheria.—Prof. Klebs, of Prague, announces that the benzoate of soda is the best antiseptic in all infectious diseases. It acts, as the experiments of the author show, very powerfully. It is claimed that a daily dose of from 30 to 50 grammes to a full-grown man will render the poison of diphtheria inoperative. The benzoate is prepared by dissolving crystallized benzoic acid in water, neutralizing at a slight heat with a solution of caustic soda, drying, and then allowing the solution to crystallize over sulphuric acid under a bell glass. Large doses do not appear to be absolutely necessary. Good results may be obtained by the daily administration of about 12 grammes.

Lime for Diphtheria.—A child in Auburn, ill of diphtheria, and whose life was despaired of, was cured by slacking lime. Small lumps of lime were kept constantly slacking near its mouth for a day and a half, until over a barrel of lime was thus slacked. The child was thought to be dying before this remedy was employed. It breathed the fumes constantly until cured.

Nutriment in Beans.—One pound of beans will support life in action as long as four pounds of rice. Two pounds of beans will help do more muscular work than three pounds of wheat, and more brain work than three and one-half pounds. The reason why beans require stronger powers of digestion than wheat is that they contain casein instead of glutin.

The Week.

The weather is becoming mors mild and spring-like, and with this favorahle cbange an advanced activity is noticed in business matters. Our wholesale dealers are receiving liheral orders from their country customers, and a hetter feeling exists in regard to trade. The prospects are very fair for abundant harvests, and the farmers are cheerful in their anticipations of the income from the growing crops, which, if the present ratee eball continue, will he fully realized.

Our legislators are working to good purpose, enacting required statutes, and mooting some doubtful points in the new Constitution.

At the hydraulic mines the severe weather for eome weeke has prevented the usual winter operations in them, and its retarding influence is etill severely felt in the high elevatious where they are located. In connection with this we append the following from the Dutch Flat *Forum*, which will he appreciated hy miners: "The injunction issued against the hydraulic miners some time ago hy Justice Jack Frost was thought to have been overruled, and the miners congratulated themselves that they would again proceed to work, hut the indications the fore part of the week cooled this idea. That old gentleman is abovs corruption and cannot he hought, but if he would condescend to melt a little toward us we would be truly grateful."

Steam Heating.—The idea of heating buildings over a large area hy steam from some central source seems to he gaiuing favor. There is prohably more in it than the public in general are aware of. The experiment of steam heating has been tried in Detroit, and pronounced a success, since which time several cities have granted privileges for the improvement, among them Cincinnati. A select committee of the Board of Aldermen of that city, appointed to investigate the subject, conoluded their work by agreeing unanimously to report the hill authorizing the laying of pipes under the streets, which the Board of Councilmen have already passed. The Committee made inquiries about the working of the system in Detroit, and all ths information they recsived was favorahle to it.

The Peculiar Gold Deposits of California.

Modes of Working Them.

As is well known, ths auriferous deposits of California occur in divers forms and under a great variety of circumstances, necessitating ths employment of many different methods and appliances for their successful exploitation. At first our miners busied themselves mainly with ths rivsr bars, shallow flats and gulches, or such other kind of placsrs as could be reached and worked most readily. As these becams occupied and impoverished, operations were gradually extended; first to the quartz veins, the hydraulic banks and the pliocene cbannels, and finally to the river beds, the deep-lying basins, the seam and the sulphurst diggings, the rewashing of the tailings and the crushing of the auriferous slates and cemsnts, the gold bluffs and bsaches and othsr strange manner of deposits having meantims received due attention.

Being so novel in form and requiring to bs utilized by devices equally novel and untried, it was a long time bsfore this class of our mineral rssources could be worked to advantage, a point that with some of them has not yet been reached. In most instances, however, ws havs succseded in handling thsm with so much profit as has eerved to draw the attention of the mining public etrongly towards them and enlist capital pretty freely in their further development.

Such being the case, something may vsry properly be said of the situation, extent and value of these deposits and the attempts that are being made to tnrn them to useful account.

As the Deep-lying Basins

Above mentioned are just now receiving considerable attention, we will first notice soms of ths efforts that are being made and the schemes projected for openiug them up and emptying them of their contents. A number of these gold-holding receptacles occnr throughout the mining districts of California, nearly all of which have been explored eufficiently to demonstrats that they would pay well if means could be found to work them effectually. Having satisfied themselves, through euch prospecting as could be easily done, that these depressions were rich in gold, the early miners made many efforts to work them through shafts, all of which proved nnavailing, more water coming in than they were able to handle. And hence it happened that many years passed before the plan of working them through tunnels or supplying adequate machinery for lifting out the water was generally adopted, hoth of these methods, according to circumstances, having lately come into use. At present several of these hasins are in course of exploration, while plans have been perfected for ths opening up of others. At a central point in the Butte basin, Amador county, a large pump and working shaft is heing sunk, and although a great deal of watsr is heing encountered, it is expected that the bottom will he reached and the works kept free of water through the aid of the powerful steam pumps employed for the purpose. In Siskiyou county a similar enterprise has been projected, but has not yet taken definite ehape. A third, however, having its site in Trinity county, and

Designed to Drain the Extensive Depression Known as Weaver Basin,

Has not only taken shape hut has made snch progrese as promises to insure the early commencement of active operations, valuable water rights and large tracts of rich gravel land having heen secured and all the surveys, maps and other preliminary work having heen completed. As this ie one of the most extensive operations of the kind ever undertaken in California and is likely to eventuate in a great success, we give the following account of the locality itself, and the means adopted for effecting its partial drainage:

This basin, which consists of an irregular depression some four or five miles across, is situated in Trinity county, Weaverville, the county seat, heing near its center. It is surrounded hy mountains and traversed by Weaver creek and its numerous trihutaries, of which its East and West Forks are the principal. It has no outlet except Weaver creek, which, escaping through a deep gorge, flows south and falls into Trinity river six miles below. Nearly the whole of this basin is composed of auriferous gravel having a great depth. Only a few feet of the surface has, however, ever heen washed, for want of fall to carry off the tailings. The Davidson flume, an immense etructurc, was huilt in the hope that it would serve this purpose, which it has almost wholly failed to do.

The plan has now been adopted of driving a tunnel through the ridge that separates Weaver basin from Trinity river, whereby sufficient fall will be secured to rnn off a deep stratum of gravel from all parts of this hasin, which for more than 30 years has heen noted for its large production of gold, it having heen one of the richest spots ever struck in the Stats. What has heen taken from it is, however, as nothing compared with what remains, if only some practicable way could he devised for getting it out cheaply.

The mining lands to be henefited by the proposed improvement compriss 11,876 acres, trihutary to which there is a water-shed covering an area of 28,000 acres. The outlet to tbsse lands has becms so choksd up witb tailings that mining can no longer be carrisd on here except in a small way. Through the construction of ths projected tunnel the business could, however, bs prosecutsd on a large scale and with great profit. This tunnel, which is to start from a point on Weaver crssk a few miles below the basin, and penstrate the ridge to the west, coming out at Steiner's Flat, on Trinity river, will be 5,148 feet in lsngth, and have a fall of 135 feet, admitting of the sluices laid in it being set on a grade of one and a qnarter inches to the box. This would take up 45 feet of the fall, leaving a dump of 90 feet. If deemed best, the sluices might be set on a higher grade, and still leavs fall enough to insure riddance of the tailings, as they would be discharged almost directly into Trinity river. Between the lower end of the tunnsl and the rivsr there is, however, plsnty of room for setting several undercurrents, and yet leave all the dump required, this being little, as the Trinity at its higher stagss of watsr carries off all the debris sent into it.

This tunnel will bs 10x10 feet, being largs enough to recsive a flums 8x8 feet, wbich latter is to carry a body of water six feet in depth flowing at the rate of 14 60-100 feet per second, discharging in that time 700 cubic fest of water. Tbis current will carry along boulders of large sizs and always prevent choking. From the upper end of the tunnel to the lower edge of Weaver basin, a distancs of about three miles, thsre is the sams fall as through the tunnel, leaving ths basin 28 feet in bedrock, and making it possible to run off the gravel at Weaverville, center of the hasin and the mines, to a depth of 123 feet lower than can be done at present. Experience here shows, bowever, that a fall of one inch to 12 feet suffices to run off tbe tailings, this heing the grade of the Davidson flume, 3,700 feet long, and wbich operated snccessfully for several years, keeping itself free as long as prevented from choking at the lower end. By adopting tHie grade the basin could be worked to a depth of 166 feet lower then would otherwiss bs practicable. The cutting of the main ditch down Weaver creek will in reality cost nothing, as this will be effected and deepened to its proper grade by mining over the ground.

Value of Mining Ground.

Ae before remarked, the surface wasbings of Weaver basin have been distinguished for their large product of gold in times past. But the lower stratum, not yet reached, is known to be much richer than the portions already run off; hesides which the bed of Weaver creek is filled to a great depth with tailings still more fertile and easily rewashed. Out of the 11,870 acres of mining ground in the basin, about 1,300 acres have been worked over, the moet of wbich is uow covered up with tailings from the higher ground. Besides lack of dump, there is encountered in the basin at various depths a stratum of cemented gravel not easily worked, which, coupled with lack of water, has tended to further cbeck operations.

Water Supply.

For introducing a large quantity of water into tbe hasin, a ditch 17 miles long has been surveyed to Stewart's fork, a portion of the flow of which, together with that of various other streams along its line, has been secured hy the projectors of this enterprise. This ditch will he 9 feet wide on top, 5 on the bottom and 5 feet deep, having capacity to carry 5,000 inches of water, which amount will be available for 8 months in the year, the supply never falling helow 1,500 inches. Along the route of this ditch one tunnel 3,000 feet in length would he required—also some rock cutting and fluming; the ground with these exceptions being favorable. It is located on a level snfficiently high to command all parts of the basin, but is not so bigh as to expose it to obstructions from snow and ice in the winter, being only 2,500 feet above sea level. It will cut on a grade of eight feet to the mile, giving it a current of very nearly five miles per hour, and a discharge capacity of 918 540 cubic feet in the same time, enough to keep the tunnel supply at an even head if properly managed. With this quantity of water a great deal of mining could be carried on in this basin where there is now but little.

The cost of building this ditch, including necessary reservoirs, etc., will he large; though nothing in comparison with the hcnefits rcsulting from the completion of the work. A good deal of money has, of course, already been expended in the purchase of mining grounds and water rights, to say nothing of cost of surveys, maps, etc. But the enterprise is in competent hands, and, possessing so much merit, will no douht readily obtain all the capital required for carrying it to an early completion.

Nevada Dividend Paying Mines.—The names of the mines that paid dividends in Nevada last year, togcther with the amount paid, is given below:

Mine.	Amount.
Argenta	$ 20,000
Belle Isle	300,000
California	1,620,000
Con. Virginia	1,350,000
Eureka Con	825,000
Independence	75,000
Indian Queen	12,000
Martin White	90,000
Ophir	100,000
Richmond Con	337,500
Total	$4,730,500

In the sculling match at Richardson's hay, Sunday last, hetween Leahy and Hoyt, ths former won in 34 minutes and 30 seconds—the best five-mile time on record.

Unwillingness of Mine Owners to Give Information.

Complaints are frequently made that mine owners are adverse to imparting information about the yield or the prospect of their mines. There is no good reason why they should be so. They indirectly act against their own intsrest by pursuing this course. By imparting information to others they stimulate them to increased exertions, and open a wider range of information for themselves. It is not necessary that they should go into the details of cost and yield so far as thsy appertain to privats business. It is not necessary for them to open their ledgers and display their profit and loss account. None but obtrusives intermeddlers would dssire to pry into private matters. But thers is a great deal of general information that could be advantageously given, which, instead of impoverishing the giver, would redound to his profit. A description of some new metbod of manipulation, an account of soms new featurs in mining, a narration of how a lost ledge was found by exploration underground, or any item that would increase the knowledge of mine working, would lead to an increased knowledge upon such matters, and to new discoveries upon points which would facilitate mining operations.

A statement of a favorable result in the work of any mine is an incentive to others to pursue a similar plan, or an inducement for them to push their prospecting still further. It would not depreciate the value of silver or gold if 20 mines of those metals were in successful operation where one now exists. Iron, copper, lead, and, in ehort, all other metals, would not deteriorate in value, if their production was greatly enhanced.

The euccess of one mine leads to tbs opening of others in the same vicinity. The result of which work is, that laborers congregate there seeking employment. Storekeepers open thcre their ehops to dispose of supplies; teamsters find their way their with loaded teams; prospectors congregate there and open new mines, giving to the oamp or district a reputation wbich it could not have gained uuder the operation of a single mine. The effect of this is, that the first or original mine is enabled to procure labor, supplies and freight at a lower rate than if it was the solitary mine in operation at that point. If no information had been given of its success, all this influx would not have occurred. Its very isolation would have retarded its advancement.

Beyond all these individual matters, tbere is a duty due to the public which demands that all information whioh does not infringe upon privacy ehould be freely disseminated. Mining is a public industry. In it, the people at large have an inherent right to receive information of its progress. They have the same right to be informed in regard to its advancement as they have to he told of the increase or dimiuution of the population, or of any other general statistics.

It is to be hoped that ths reticsnce of mins ownere will soon pass away, and that they will perceivs that their churlish method of withholding intelligence does not redound to thoir benefit.

Tuscarora Mines.—Mr. E. M. Hall, Secretary of the Grand Prizs and other Elko county (Nev.) mines, furnishes to the *Bulletin* the following statement of hullion product of 1879 of the mines represented in his office:

	Gold.	Silver.	Total.
Argenta	$ 4,423	$ 80,770	$ 85,103
Belle Isle	54,382	503,435	557,817
Endowment	.....	20,848	20,848
Grand Prize	17,720	290.729	308,455
Independence	13,238	239,992	253,230
Leopard	1,205	38,859	40,064
Navajo	1,087	17,182	18,269
Totals	$92,061	$1,191,815	$1,283,876

The product of the Argenta mine is for January, May and June. No hullion was turned out in the other months of the year. There was a valne of $5,071 of Belle Isle ore crushed hy the Grand Prize mill in January, hut the remaindcr of the product was the result of the crushing in the last seven months of the year. Out of the total product of this mine for that period, stockholders received $300,000 in dividends. The yield of the Endowment mine was mads in January, March, October and Decemher. This mine is in Esmeralda county, Nevada; all the others are in Elko county. The Grand Prize mine yielded bullion in every month of the year, except May, Novembor and Decemher. The Indenendence mine produced nothing in January, November and December, hut yielded in all the other months, and paid $75,000 in dividends to stockholders. The Leopard mine produced during six months of the year, mostly in the last half. The product of the Navajo mine was for Novemher and December. The Argenta collected $30,000 in assessments in 1879; Endowment, $25,000; Grand Prize, $125,000; Independence, $25,000; Leopard, $100,000; and Navajo, $20,000.

The Arizona Republicans have selected ex-Governor Safford and Levi Bashford as the delegates to thc Chicago Convention.

News from the Skagit mines is to the effect that from five to six feet of snow covers the ground on Ruby creek.

Legislative Matters.

The best thing the Legislature has yet done is the repeal of the obnoxious Boiler Inspector bill, a measure which passed four years ago, but never was put into operation. It gave the inspector a very fat office, some $35,000 a year, and made him an autocrat over the destinies of the iron business in this city. The foundrymen will breathe a sigh of relief to know that there is no longer a possibility of extortion in this direction. A hard fight had to be made, however, to secure the repeal of the bill.

In the Assembly, Brusie has introduced a bill authorizing Supervisors to establish the price of water in placer and hydraulic mines.

Satterwhite has brought in a bill which provides that any private person may, by action, inquire into the due incorporation of any company, a matter before only in the power of the Attorney-General.

Mr. Chase's new bill requires that 10% of the capital stock of corporations shall be paid in before the act of incorporation.

Gorley's bill, to compel officers of stock corporations to sell to the highest bidder, has been withdrawn.

The Committee on Mines and Mining have reported favorably on Bill No. 57, regulating the sale of mining stocks.

Fox's bill, relating to the removal of mining company officials, has been reported on favorably; also Felton's bill, relating to purchase and alienation of mining lands.

Bill No. 248, relating to the removal of mining directors—one-fourth of the stockholders to call a meeting, instead of one-half, as now—has been reported upon favorably.

In the Senate three bills have been introduced by Mr. Johnson by request, relative to debris. One is in relation to the parties to, and place of trial in actions for injuries arising from tailings or debris from the mines. Another is an act to prevent the running of tailings upon lands of another, making it a misdemeanor. Another is an act relative to parties in action to recover damages from injuries from the flowing of tailings. All three of these bills have been referred to the Committee on Water Rights, Irrigation and Drainage.

Hittell's bill providing for the removal of officers by a majority of stockholders in mining corporations came up.

Conger offered an amendment giving actual holders or owners of stock the right to vote and take part in the proceedings, notwithstanding that the stock is held in the name of a trustee.

Traylor opposed the amendment on the grounds that it would increase the evil that it sought to remedy.

Neumann also spoke against the Conger amendment, stating that if a man held stock and desired to take part in the business of the corporation, he should see that his name is on the books.

Traylor said that to allow holders of stock to vote, would be to allow parties who had borrowed stock, with no interest in the corporation, to attend meetings and control them.

Nye could not understand why trustees should be allowed to vote if holding no interest in the corporation.

Enos supported Conger's amendment as one means which would remove the dishonesty that characterized stock operations.

Johnson said he would give *bona fide* stockholders the right of voting, but he could not see how the amendment would accomplish the object sought, because in the first section of the bill it was required that names on the books of the corporation were evidences of ownership.

Hittell explained that the difficulty under the old law was that the books were closed ten days before the day of meeting, whereas under this bill the holders of stock, if properly indorsed, can have their names inserted in the books of the company five minutes before the time of meeting.

The amendment of the Committee on Corporations, that only those whose names appear on the books of the corporation shall have the right to vote, was adopted.

The amendment offered by Conger was defeated—ayes 8, noes 15.

Enos moved to amend Section 1 by striking out the words "on the books," thus giving holders and owners the right to control, whether their names appear on the books or not. Lost—ayes 11, noes 14.

After some further discussion the bill was recommitted to the Committee on Corporations.

The Assembly Committee on Mines and Mining has agreed to report favorably on Gorley's bill, regulating the sale of mining stock. The principal provisions of the bill are as follows:

"An act to limit and regulate the sale of mining and other stocks." First—All purchase and sale of shares of any incorporated company, under the laws of this or any other State, in any stock board, mining exchange, or auction mart, in this State, is hereby prohibited other than in manner herein prescribed, and every violation of this act is declared to be a felony, except as hereinafter prescribed, and upon conviction in any court of competent jurisdiction, shall subject the offender to a fine of not less than $1,000 nor more than $10,000, and imprisonment in the State prison not less than six nor more than 12 months, at the discretion of the Court.

Second—All sham or wash sales and all sales where there is no money, or where there is less than a full money consideration paid, accompanied by a surrender of all stock of shares bought and sold, are hereby prohibited.

Third—It is hereby made incumbent upon all stockbrokers to furnish their customers within 48 hours (Sundays and legal holidays only excepted) after making such a sale or purchase, a written or printed list of the stock or shares sold or purchased for such customers, specifying the session of the stock board at which such sale or purchase was made, stating the true purchase or sale price, and also the number of the certificate of stock sold or purchased.

Fourth—Brokers are hereby prohibited from using, loaning, hypothecating or selling any stocks on hand belonging in whole or in part to a customer; but they shall hold all stocks that may come into their hands, belonging in whole or in part to their customers, inviolate, and shall at any time, upon demand and upon payment of all arrearages upon the same, deliver up the identical stock purchased for him, and none other.

Fifth—The Secretary or Clerk of every stock board, stock exchange and auction mart, shall keep a correct list of all stock transactions in his board, exchange or mart, shewing the name of the seller and purchaser, the number of shares, and the price at which the same was sold and purchased; and this record, so kept, shall be open to inspection during usual business hours to any and every person having stocks bought or sold in such board, exchange or mart; and it is hereby made the imperative duty of such Secretary or Clerk to furnish to such customer or customers, upon demand and upon payment of the Notary's fee therefor, a sworn statement of the transactions of any session or sessions of said board, exchange or mart, and, upon failure to furnish such sworn statement, such Secretary or Clerk shall be deemed guilty of a misdemeanor; and, upon conviction, shall be subject to a fine of not less than $100 nor more than $1,000, and shall be imprisoned until such fine is paid or satisfied.

Foundry Notes.

The Pacific Iron Works have recently been turning out a very considerable amount of mining machinery of various kinds, among which is a larged sized Howell-White furnace, with salt feeders, shafting, pulleys, etc., for the Ontario mine, in Utah.

They have also sent recently a Howell-White furnace to the Bajada mine, Mexico.

A ten-stamp silver mill in sections, and very complete, has been shipped by them to Peru, a duplicate in style to the 80-stamp mill built by them for the Cerro de Pasco mine a year ago.

They are also building a water-jacket copper-smelting furnace for the San Francisco copper company of Nevada county. Several copper and galena ore furnaces are being built for various parts of Arizona.

The works have now on hand a 20-stamp silver mill for Globe district, Arizona, with pumping and hoisting machinery for the same district.

POSTAL INDEX.—A little publication of great value to those who write letters (and who does not?) is the "Pacific Coast Postal Index," just published by L. P. McCarty, Box 2,272, San Francisco. It gives a full list of Pacific Coast postoffices and express offices, the county and State in which each is located. It also gives the rates of foreign and domestic postage. Now that the Government is extra anxious that every letter should be properly addressed, it is well to have an "index" to give all the points. The "P. C. P. Index" can be had for 20 cents by sending to the publisher as above.

The Centrifugal Creaming Machine.

The interest in the reported revolution in butter making, which promises to banish pans, racks and cream jars from dairy practice, leads us to present sketches of one of the devices lately brought out in Europe for removing cream by centrifugal motion. The engravings are not as perfect as we would like to have had them, but we hope from them and the description below, some general idea can be had of the way in which the skim milk is thrown away from the cream, and both forced to deliver themselves in separate streams.

It will be understood from the engraving, Fig. 1, that the case, standard and base plate are in one casting, so that the bed plate may be bolted to the floor or framing of the intermediate motion. But details in fixing the separator will depend upon the motive power, the position of the separator itself in the dairy, and other circumstances which dairy farmers will have no difficulty in determining, as the whole is simple and capable of any application, so that each dairy may have its own plan in fixing the intermediate motion and separator if necessary.

In the engraving, Fig. 2, *A*, is the rotating chamber in which the separation of the milk and cream takes place. It is made of best Swedish steel, forged into the form of an oblate spheroid and then turned truthfully inside and outside.

The chamber, *A*, is fixed on top of the vertical shaft, *K*; the lower bearing of *K*, is on a small piece of cork in a friction cup in the top of the spindle, *h*, of the driving pulley, which has an adjustable bearing, *i*, below, as shown in the cut. The upper part of the shaft, *k*, rotates in the stuffing box, *g*, provided with an elastic packing ring and self-lubricating cup. The bearings of the pulley spindle, *h*, are also self-lubricating. The cover, c, of the chamber, *A*, is in the form of an inverted funnel, the mouth of which is bolted to the top of the chamber by four bolts, two only of which are seen in the section—Fig. 2. To prevent the atmospheric action of the nuts of the bolts inside the case, a cap (not shown in the cut) fits neatly over them. Immediately below c, is another funnel with a pendant tube, *b*, from one side, as shown in the illustration. The former, *c*, *c*, is the milk funnel, and the latter the cream funnel. A broad collar fits loosely on to the top of *c*, *d*, for the purpose of guiding the milk into the receiver, *B*. The top of the cream funnel is also surrounded with a collar for guiding the cream into the receiver, *C*. The receivers, *B*, and *C*, are of the nature of funnels, each having a discharge pipe. They are made separately of white metal, the pipes forming handles. *B*, fits on easily to the top of the lid of the outer case, and *C*, fits on to *B*, whilst a cover fits on to *C*. The receivers, *B* and *C*, being circular, the discharge pipes can be placed to deliver the milk and cream on any side of the separator, either both set for discharging on one side or on opposite sides. The supply tube, *a*, is screwed into the bottom of the chamber, *A*, centrally with the main vertical shaft. It has two discharge pipes, opposite each other as shown in the sectional view. The upper end of the supply pipe rises a little above the cover—best seen in the profile at the top (Fig. 1,) with sufficient space all round for the escape of animal odor.

The vessel for supplying the whole-milk is not shown in the cut, but the cock will be understood as proceeding from it. The mouth of the cock is held in position by a three-legged stay, not shown in the section.

In the internal arrangement of the separator there are three concentric tubes, to which special attention requires to be called. First, there is the central tube, *a*, down which the milk flows, with its two exits at the bottom of the chamber, *A*. Second, there is the cream tube which surrounds *a*; and third, the milk tube, which surrounds the cream tube. All the parts, tubes, collars and funnels, are so designed as to be easily taken to pieces for being cleaned and put together again for work by any unskilled laborer—the only education required being to see the thing once done.

FIG. 1.

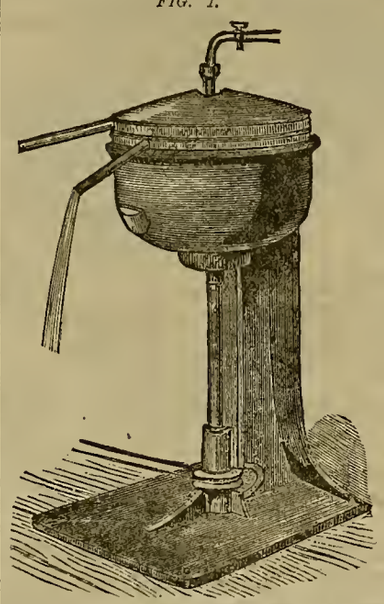

FIG. 2.

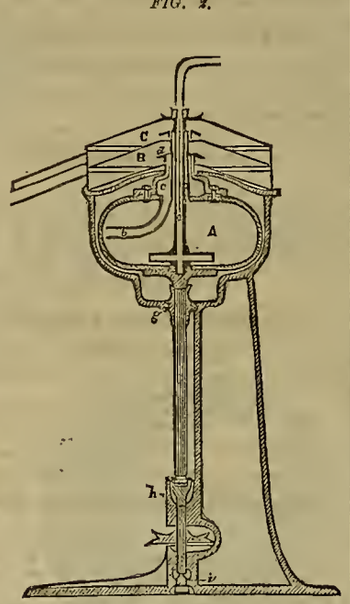

THE LAVEL CENTRIFUGAL CREAM SEPARATOR.

The action of the separator is as follows: When the power is turned on, the application being by friction gear throughout, the speed gradually rises, and when the chamber, *A*, attains about 6,000 revolutions per minute the tap above is opened, when the milk flows down into the chamber, *A*. The calculated speed is, of course, determined by the intermediate motion, and it is easy to see when this has been communicated to *A*. Thus at first the mouth of the supply pipe at the top is seen to move, but when once the desired speed has been attained it appears at rest, like a top when spinning at full speed; and, like the top, too, it stands vertically erect, as if at rest, without any vibration, although making 8,000 revolutions per minute, which is about the maximum speed. But to effect this, in fixing the separator the common axes of the pulley spindle, *h*, and the main shaft, must be vertical. To insure this, the mouth of the outer case, on to which the lid fits, is turned true at right angles with the central axis. This being done, the outer case can be properly fixed by a spirit level. The work of fixing is thus simple, but it has to be accurately done.

The separation of the milk from the cream is effected within the chamber, *A*, by centrifugal action. The cream and milk mixed together as they come from the cow are thrown toward the walls of the chamber, where the separation commences. Close to the small supply pipe, *a*, about an inch in diameter, centrifugal force is almost *nil*. It is necessary to bear this closely in mind in order to comprehend the course which the globules of butter take on their way to the exit from the place in which they are first deposited in the chamber, *A*. The (so to speak) skim-milk tube is fed from the outer portion of the revolving contents, and the cream tube from the inner portion next the axis. It is there the cream finds itself, owing to the denser milk being thrown outwards; and the escape being urged both by centrifugal action and head pressure alike, the outer and inner portions of the contents are delivered by two different tubes at two different spouts, the one of them rich and the other poor in butter globules. The milk, thus delivered free from cream, yields, in fact, less butter than skimmed milk when the cream is raised in the common way.

Without going further into the consideration of this subject, the path of the butter globules is no doubt an upward curve toward the exit. Were a chamber made with side walls of glass sufficiently strong to bear the speed of 8,000 revolutions per minute, the path of the cream would be seen, whilst the more important question would be determined as to whether the form of Mr. de Laval's chamber is the best that can be made in its minor details. In principle, its construction appears to be sound, and the small percentage of butter left in the milk may be taken as presumptive evidence that the whole may yet be removed by the inventor. The principle of construction practically is two-fold—first, the separation of the milk by the tube, *b*, at the extremity of the radius of an oblate spheroidal chamber revolving on its minor axis; second, the removal of the cream by a central tube surrounding the entrance pipe.

The milk and cream are discharged above, each in a very thin sheet, by centrifugal action. The receivers, *B* and *C*, with their respective collars, are stationary, and incline each downward, in the form of an obtuse cone, to the spouts. Down these inclines the milk and cream flow, spreading thinner and thinner towards the perpendicular rim of *B* and *C*, thus affording a ready means of escape for animal and other odors and gases, and without the milk coming in contact with the atmosphere, which is objectionable, especially when it (the atmosphere) is loaded with microscopic germ life, as it generally is.

When all the milk has been separated from the cream, the speed of the rotating chamber is allowed to slacken. A portion of the separated milk is then put into the supply vessel, and as this flows down through *A*, into the chamber, it forces up the cream by head pressure, and thus all the fluid is put through.

Separators are made of different sizes. The size shown at Kilburn is 11 inches by 4 inches inside, and holds 10 pints. It separates about 30 gallons per hour, and the price, $140, is exclusive of the intermediate motion, the cost of which will depend upon how the separator is fixed. Hand machines are so easily driven that they can be worked by a foot-treadle, like a spinning wheel. Besides separating cream and milk, the machine will separate other liquids of different specific gravity, such as tar from water, etc.

THE steamer *Bengore*, from Penarth for Gibraltar, foundered when two days from port, drowning 13 persons.

PARNELL delivered an address Monday evening in the hall of the House of Representatives at Washington.

DURING January the public debt of the United States was decreased $11,014,263.

Our State Fish Farming.

From the biennial report of Hons. B. B. Redding, S. K. Throckmorton and J. D. Farwell, Fish Commissioners, we extract the following items relating to the progress of pisciculture in this State:

There is reported an increasing public interest in fish culture and in the efforts of our Commissioners to continue the supply of valuable food fish in our waters. The destruction of fish during their seasons of reproduction, in defiance of law, once thought to he hut a venial legal offense, is beginning to he considered a serious crime. As population increases, and railroads and other means of transportation are extended, there is a larger demand for fish; this is met hy an increase in the numhers of fishermen, hy extending the area of the fishing grounds, and hy improved processes of capture.

One-half of the annual appropriation placed at the disposal of the Commissioners is expended in the hatching of salmon eggs and placing the young fry in the trihutaries of the Sacramento river. From the organization of the Commission, and including the year 1879, there has been hatched and turned into the Sacramento river, 13,150,000 young salmon; these, added to the natural supply, have heen sufficient to make them as numerous in the river, during their seasons, as they have been at any time since so large an area of their spawning heds was destroyed by the operations of mining. If there could he a faithful observance of the law that prohihits the catching of salmon during the close season; if the fish could have the river free from nets during these six weeks, and he allowed in peace to reach their spawning grounds, there would he no necessity for an increased appropriation, even if canning establishments were doubled and fishermen mnltiplied in the same proportion.

Through the kindness of Prof. Baird, U. S. Fish Commissioner, there has heen received from Lake Michigan, as a donation, nearly 1,000,000 eggs of white fish.

Some of the previous importations of these fish, planted in Tahoe, Tulare and Clear lakes, have thrived, and a few mature fish are reported as having been caught in each of these lakes. All of these bodies of water will, without doubt, within a few years, be stocked with this valuable fish.

In June, 1878, there were received from Prof. Baird, U. S. Fish Commissioner, from Havre de Grasse, 115,000 young shad; these were placed in the Sacramento river, at Tehama, where all previous importations have been planted.

In 1874, the Commission imported from the Raritan river, and placed in lakes near Sacramento, 74 Schuylkill catfish. They have increased to millions and furnish an immense supply of food. They have hecome so numerous that they are as regularly on sale in the city markets as the most abundant native fish, and are sold at ahout the same prices. They thrive in our rivers and lakes, and in the still-water sloughs of our plains, as well as in the brackish sloughs in our tule lands. They appear to he equally at home in lakes on the mountains and in artificial reservoirs in the valleys. Many farmers who have natural ponds on their farms, or who have surplus water from wind-mills and have made artificial ponds, have stocked them with this excellent fish.

In January, 1878, there were received from the United States hatching-house of Grand Lake Stream, Maine, 50,000 eggs of the land-locked salmon.

As they are natives of the cold lakes of Maine the most appropriate places for the distrihution of the young fish would he in our mountain lakes; hut, for the purpose of testing their fitness to thrive in warmer waters, a portion were also distributed to lakes in the valley and on the coast.

In January, 1878, and in Jannary, 1879, we received from Wisconsin and New Hampshire 70,000 eggs of Eastern brook trout. The young fish were hatched at the State hatching-house, San Leandro, and were distrihuted throughout the State.

The Commission has heen unahle as yet to introdnce the king carp, with which to stock our inland slonghs and warm water lakes. This, the most valuahle variety of the carp family, was imported from Germany hy Prof. Baird, United States Fish Commissioner, a few years since, and has increased to large numbers in ponds at Washington and Baltimore. They could not he obtained in July, at the time Mr. Stone left with fish for California. They hope to receive the Stato's quota in June, 1880, with another consignment of young shad. It is certain they will thrive in California, as another variety of carp, imported as a private speculation some years since, has heen extensively distributed over California, and now furnishes a large amount of food to people in the interior valleys.

A few suits have heen commenced to compel the owners of dams to construct fish ladders. In almost all cases, when notified, the owners of dams have complied with the law. It is generally understood by the people of the State, that to preserve fish in our rivers, it is ahsolutely necessary that fish should be allowed to reach their spawning grounds.

The report concludes with an essay by W. N. Lockington on the food fishes of San Francisco. Those interested in the subject could douhtless obtain the document by addressing the Commissioners.

(Opposite Masonic Temple.)
Watches, Jewelry and Diamond Work, Badges and Medals, For sale and made to order.
Quartz, Turquois and other Stones cut and set.
Watches and Jewelry repaired by skillful workmen.

Testing and Working Silver Ores.

The above is the title of an illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron, which has been issued by Dewey & Co. Mr. Aaron has managed to give many useful hints and suggestions free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope:

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working sample, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, bas something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles, Smelting, Mexican process, Chilean process, Krochnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mecbanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

The book is a serviceable one for miners' and prospectors' use. Price, post free, $2.00. Address Dewey & Co., MINING AND SCIENTIFIC PRESS, 202 Sansome Street, San Francisco.

The Explorers' and Assayers' Companion.
(THIRD EDITION.)—NOW READY.
468 octavo pages, bound in library or pocket size. Price, $6

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Action; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Large Octavo. Over 153 Illustrations.

By ROBERT GRIMSHAW, Ph. D.,
Member of the Jury on Wood-working Machinery at Paris Expositiou of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small band, sash, Mulay, jig, drag, circular, cylinder and haud Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaging, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 96 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed

Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the subscription price is this date made $2.00, postage paid, up to date of publication, after which time full retail price will be charged. In press Orders received now at subscription price, $2.00.

ROBERT GRIMSHAW,
624, 626 and 628 Market Street, Philadelphia.
January 1, 1880.

ST. DAVID'S.
A FIRST-CLASS LODGING HOUSE.
CONTAINS 113 ROOMS.
715 Howard St., near Third, San Francieco.

This House is especially designed as a comfortable home for gentlemen and ladies visiting the city from the interior. No dark rooms. Gas and running water in each room. The floors are covered with body Brussels carpet, and all of the furniture is made of solid black walnut. Each bed has a spring mattress, with an additional hair top mattress, making them the most luxurious and healthy beds in the world. Ladies wishing to cook for themselves or families, are allowed the free use of a large public kitchen and dining room, with dishes. Servants wash the dishes and keep up a constant fire from 6 A. M. to 7 P. M. Hot and cold baths, a large parlor and reading room, containing a Grand Piano—all free to guests. Price single rooms per night, 50 cts.; per week, from $2.50 upwards.

R. HUGHES, Proprietor.

At Market Street Ferry, take Omnibus line of street cars to corner Third and Howard.

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claim from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco

To Railroad Men, Mining Superintendents, Street Railroads and Lumber Dealers!

Ingersoll Rock Drills.

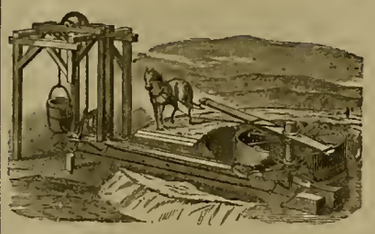
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.

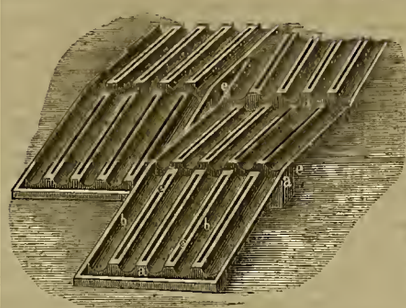


MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.
The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing

REYNOLDS & RIX, 49 Fremont Street, San Francisco.

Howland's Under-current, Mill and Sluice Riffle.



This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

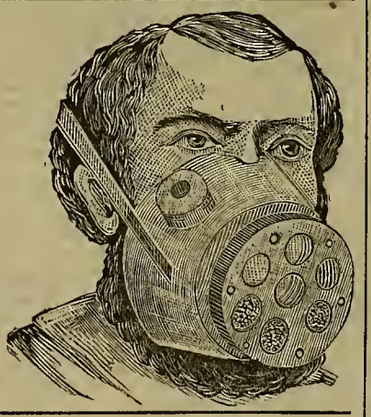
STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

PATENT

LIFE-SAVING RESPIRATOR

Prevents Lead Poisoning and Salivation.



INVALUABLE to those engaged in Dry Crushing Quartz Mills, Quicksilver Mines, Guano Works, White Lead Corroding, Feeding Threshing Machines and all occupations where the surrounding atmosphere is filled with dust, obnoxious smells or poisonous vapors. The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, $3 each, or $30 per dozen. Sent post-paid to any address upon receipt of price.

SETH MARSHALL, Jr., Agent,
309 California Street, San Francisco, Cal.

Send for Descriptive Circulars containing testimonials of well-known parties who are at present using them.

Sanderson Bros. & Co.'s

BEST REFINED CAST-STEEL.

WARRANTED MOST SUPERIOR FOR DRILLS, HAMMERS, ETC.

A full and complete stock of this reliable and well-known brand of Steel, for mining and other uses, now in stock, and for sale at

21 and 23 Fremont Street, S. F., - H. D. Morris, Agent.

Assaying and Testing Taught.

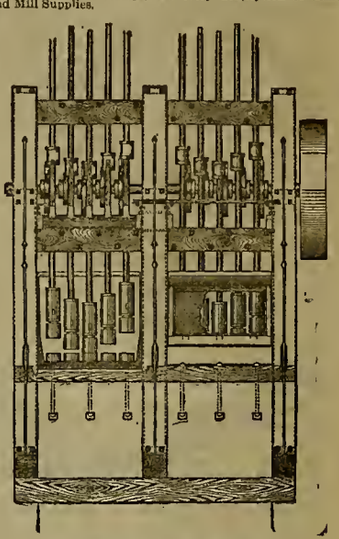
AN ENGINEER,

Favorably known in the East, desirous of settling in California, seeks position as Superintendent or Chief Draughtsman. Competent to design Stationary, Marine, Locomotive, Mill Work, Sugar and Hydraulic Machinery. Speaks Spanish. Unexceptional references. Address EXPERT, this office.

Machinery.

GOLD AND SILVER
Grinding and Amalgamating
MACHINERY.

Stamp Mills, Rock Breakers, Crushing Rolls, Amalgamating Pans and Separators for Gold and Silver Ores, Chlorodizing Furnaces, Retorts, Rock Drills, Air Compressors, Steel Shoes and Dies for Stamps, and every description of Mine and Mill Supplies.



SPERRY'S
Wrought-Iron Frame
FOR STAMP MILLS.

Great saving in time and money over the wood frame. Is made complete with wrought-iron frame ready to put upon the foundation, requiring no skilled millwright. These mills are unsurpassed in excellence in every particular.
We are furnishing all the Machinery for a 10-Stamp Gold Mill, including Crucible, Steel Shoes and Dies, Boiler and Engine, Counter Shafting, Pulleys, etc., Stamps weighing 450 lbs. each, with Copper Plate inside of the Mortars, and for tables outside, making all the Machinery complete for a 10-Stamp Mill for the sum of

$2,550.

We construct Mills with Stamps weighing from 350 to 900 lbs. for gold or Silver Ores. Wet or dry Crushing Mortars. Will contract to erect complete Gold and Silver Mills on the most improved plans. We have 30 years' experience in mining and milling Gold and Silver Ores, and can compete with the world. Send for a circular. Address

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city:
Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Hueme, John Marquis, B. McDougal & Son, Wm. Mooser, Wm. Curlett, Meeker & Banks, W. C. Hoagland, S. & J. Newsom, B. Henrickson.

Mines and Works of Almaden.

Translated from "Annales des Mines"

BY S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (post-paid) 50 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

[CONTINUED FROM PAGE 85.]

said to he one of the finest prospects in camp. On the Ada, Cochise, Ella, Pensacola No. 2, Waco, Falcon, Wabash, Mazeppa, and many others work is being steadily pusbed.

BLUE TOP.—Tbis claim, situated west of the Alta, in Patagonia district, was sold last week by Dan Rooney to Messrs. Williams and Topliff, of this place, for the sum of $7,000.

REDEEMER.—The Redeemer is situated two miles north of old Cerro Colorado camp. The entire lode, 6,000 ft, carries the same character of ore, gray carbonates and sulphurets, giving an average working assay from 25 pounds of rock, of $110. A tunnel 300 ft, run on a cross lead, shows ore all the way.

HEINTZELMAN.—Work will soon be resumed on the old Heintzelman claim, and the shaft sunk from its present depth, 200 ft, to a depth of 500 ft. There havo heen two very large pockets of native silver found in this mine.

ORO BLANCO ITEMS.—*Arizona Star*, Jan. 29: The main shaft in the Warsaw is down 140 ft, and has a good showing of ore on the bottom. The Alaska shows five ft of ore at the bottom of the 205-ft shaft; the tunnel to strike the other vein at 230 ft, perpendicular depth, is in 375 ft. A Red Oak, Iowa, company is doing work on the Californian mine, which is showing up splendidly. The Austerlitz has two 50-ft shafts, at the bottom of which drifts are being started. The ore is found in a vein of from two to three ft in width, and gives a good showing in gold. The Osceola company are working the Peelstick, which has a 115-ft shaft, from which a 75-ft crosscut has been run. The crosscut has reached a body of ore five ft in width. The same company are commencing a shaft on the Osceola mine.

COLORADO.

ROBERT E. LEE.—Boulder *News and Courier*, Jan. 23: On the 13th inst., this mine, which is located at Leadville, put out 95 tons of ore in 17 hours, and the ore yields an average of over $1,250 per ton, or an aggregate of $118,500 for the day's work.

SILVER STAR.—Fairplay *Flume*, Jan. 22: This mine has made one of the richest strikes in Park county. It is located on Copper mountain. It was bonded for $6,000

SILVER KING.—Silver Cliff *Prospector*, Jan. 27: The shaft is down 20 ft, sbowing very fine ore. Threo assays of ore from the lode run 120, 57, 67½ ounces silver to the ton.

RATTLESNAKE.—Ruby silver was found in the lode. The specimen exhibited is as rich as any we have yet seen.

ROBERT BURNS.—Has struck a large veiu of galena as rich as any discovered in this section.

IOWA.—Is in the chloride belt; has an abundant supply of rich ore, and is turning out more thau ever.

SUNRISE.—Shaft down 115 ft, and being worked with the most encouraging results, ore running 400 ounces silver, being the output from a vein four ft in thickness.

LADY FRANKLIN.—The company have sunk a shaft 60 ft. At this depth a drift was started northwest, which has reached 65 ft, and a shaft is being sunk at the extremity of the drift where a vein four ft in width containing carbonates has been cut.

REPUBLICAN.—Shaft down 23 ft, at which depth a well-defined vein eight ft in width, carrying gray copper which runs 100 ounces silver, has heen cut.

WEST MOUNTAIN.—Chlorides running high in silver have been found. It is contiguous to the Cliff lode.

HEATHEN DUTCHMAN.—Has struck ore which is valued at 400 ounces to the ton.

CALIFORNIA.—Ore now taken out assays 3, 8, 84, and 265 ounces silver to the ton.

SILVER HORN.—Tests of ore, taken without selecting, show 12, 4, 10, 152, 1,850 and 3,540 ounces, with an improving richness in quality and quantity as development progresses.

RACINE BOY.—Six silver bricks, weighing 20 pounds each have been made from a five days' run of the mill, and more are to come.

POLONIA.—Denver *Mining Review*, Jan. 22: Shaft down 102 ft; 1st level, 30 ft above. Sump at 72 ft showing ore of $100 value. The vein at this depth is from 2 to 16 inches wide.

BUNKER HILL.—Shaft down 86 ft; ore veiu, 12 inches; character of ore, galena, iron pyrites, gray copper; value, 70 ounces per ton.

OREGON.

MINING ITEMS.—Jacksonville *Sentinel*, Jan. 28: Piping at the dry diggings, at Crant's pass, is going on night and day with a full head of water. Keaton & Klippel, on Poorman's creek, are working with a good head of water and prospects flattering. The Squaw Lake Co. have heen interrupted by slides, but Supt. Klippel expected to be piping again on Saturday last. Miners on Foot's creek are tearing the dirt up in that camp at a lively rate. Plenty of water and a good prospect for a harvest of dust. Jackass creek is unusually flush and every miner is busy. A very large amount of the rich dirt of that camp will be moved before the season ends. Sturges & Co. have a force of 16 men ground sluicing in their two claims, and have already moved more dirt this season than was moved all last winter. Pipe laying at the '49 diggings, owned by E. K. Anderson, was completed on Saturday and work commenced in earnest. Thos. Kahler brought into town yesterday, a nugget of gold and quartz weighing five and one-half ounces. It was taken out at the Fort Lane diggings, and is worth about $60. The operations of the Sterling hydraulic company have been retarded by numerous slides in their ditch owing to melting snow. The English aud Blue Gravel companies, on Calico creek, are piping with a full head of water, and moving immense quantities of dirt. Oreen Bros. are again crushing rock from the Sugar Pine ledge; work having heen suspended for a short time during the frecze. Ecklesou & Chappel have a full force on their claim working night and day with an amplo hydraulic head of water. The Kahler & Lackland claim, on Applegate, are now running night and day. The pipe is tearing up ground that prospects exceedingly well. The Willow Springs camp has still abundant water, every miner being husy. The arrastra of Egan & Co. is still crushing good rock with the best of prospects for plenty more. Thos. Mee, on Foot's creek, is working his small hydraulic very successfully with a prospect of a rich clean-up. More than wages is picked up daily in pieces weighing from $2.50 to $5. Saltmarsh & Co., on Sterling creek, have a splendid head of water, and are keeping it busy ground slicing. This company use a small pipe with a light pressure to facilitate moving the dirt in the ground sluice.

PRODUCTION AND TRADE.—The "Annual" of he San Francisco *Journal of Commerce*, which was issued Jau 24th, is in some respects the most valuable trade paper ever issned in this city. In addition to the usual review of the market course of different articles of produce and merchandise during the preceding 12 months, there were this year tables occupying two of the mammotb pages of the *Journal*, giving the exports of this port for each of the last 12 years, the countries to which the exports were made, etc. These were from the recorde of the Merchants' Exchange, and afford an opportunity to etudy the courses of the city's commerce, which has never heretofore heen enjoyed by the public.

ARRANGEMENTS for a royal procession are making in London on the occasion of the opening of Parliament, Feb. 5th.

THE death of Very Rev. Frederick Oakley, a Catholic writer on religious subjects, is announced.

Hofmann's Patent Process.

EDITORS PRESS:—Allow me once more to troubls yon for a space in your paper in relation to articles concerning Hofmann's process. Mr. Aaron argues that the "Hofmann process is not a combination but a succession of known processes; they are coupled not combined." I think Webster could not have done better. Patents on a combination (or coupling) of by themselves not patentable processes like Hofmann's patent, are just as sound as patents on new inventions. The combination is simple of course, but effective. Mr. Aaron states that he extracted $50 worth of gold out of $84 by the Patera process. This is over 50%, and proves that the gold was es a chloride in the ore, and in this case the Patera processs certainly must extract it.

I always considered that Mr. Aaron knew what he was writing about, if intended for publication, which seems not always to be the case; end I wonld advise Mr. Aaron to be more careful in future and to bs sure of the truth of what he is writing. He professes to be in possessiou of a pile of my tailings assaying $28 per ton. I do not dispute the $28 if Mr. Aaron found so much by assay, but who informed him that those tailings are from my treatment? Mr. Aaron is the fifth Superintendent at thoss works since I left, and if he finds pilcs of tailings there, I am sure they smelt all aliks, consequently he had no means to find out which is which, hnt it just suited him on the present occaeion to attribute it to me. If the Hofmann process had been known and applisd at that time when the ore of those tailinge was under treatment, the tailings would certainly not assay $28. In conclusion I wonld remark as to his sign of interrogation, that ons person has the same right to defend as the othsr to ettack.

Mr. Deetken took up the pen in a very bad humor and substitutes my worde too often with others that suitcd him better. He denies that he wrote the following in his first letter: "I find an article (on treatment of gold ores by Hofmann) coneisting of an application of the Patera process precsding the Plattner process with salt roasting, as introduced by me at ths Eureka mine." Mr. Deetken says this means that he iutroduced ths salt roasting. After many words without interest he undertekes to look iuto the facts, and there he discovers that Hofmann, after extracting the silver, wae surprised to find his "tailings" rich in gold and takes refuge in the Plattner process. Then it troubles Mr. Deetken whether Hofmann's "good way of treating ore" could be a new process or not, and whether Hofmsnn would still claim it his patent if the Kiss process were substituted by Patera's in his combination, and wants ms to answer tbe important question, while he knows himself well enough that wbat is not expressed distinctly in the patent can not be claimed.

I am glad to heer from Mr. Deetken thet he has no patent on Plattner's chlorination, because until now many persons thought he had; but in regard to his "system of apparatus" and the insolent expression that I used his fixings, which be calls a "system," I refrain from further explanation on account of the pending lawsuit.

The "conclusion" of Mr. Deetken in turning the table and ths elegant style of his writing show that he was not in his normal condition while writing; nevertheless I will tell him that I did consent to take in some of his experiences in chlorination in my publication, giving him always credit, as it was my object to introduce to the mining pnblic a young man who went through a polytechnic school and tried his luck in a branch of metallurgy new to him, in which he was instructed in Grass Valley by Mr. C. V. Bescler, a graduate of the Royal Mining Academy at Schemnitz, where the chlorination of gold sulphurets was practised. G. KUSTEL.

Bullion Shipments.

Since our last issue, we have noticed the following bullion shipments:

Richmond, Jan. 27, $11,328.08; Jan. 25, one week, $29,014.12; Wells, Fargo & Co. Eureka, Jan. 25, $2,551.95; one week, $14,846.84; Eureka Con., Jan. 25, one week, 229,280 lbs.; Jan. 27, in three days, 74,185 lbs.; Wells, Fargo & Co. Pioche, Jan. 25, one week, $7,334.13; at Eureka, Jan. 30, $2,000; Con. Virginia, Jan. 27, in Jan. to date, $136,560.75; Jan. 30, $3,025; Wells, Fargo & Co., Jan. 27, $1,100; Belmont, Jan. 27, $4,399; Hillside, Jan. 29, $5,200; Paradise, Jan. 29, $3,913.94; Owyhee, Jan. 29, $2,500; Californie, Jan. 31, $57,454.64; Ophir, Jan. 31, $14,558.41; Sierra Nevada, Jan. 31, $14,545.28; Union Con., Jan 31, $25,595.03; Northern Belle, Jan. 28, $6,387.03; Christie, Jan. 24, $2,220.45; Jan. 27, $1,989.14; Jan. 30, $2,054.53; Ontario, Jan. 23, $3,374.81; Jan. 24, $3,143.29; Jan. 26, $7,099.08; Jan. 27, $4,757.09; Jan. 28, $4,776.99; Jan. 29, $4,629.55; Jan. 30, $3,274.76; Yosemite, Jan. 24, $2,500; H. S. M. Co., Jan. 24, $10,000; Jan. 26, $7,500; Jan. 28, $5,000; Morgan & Germauia, Jan. 24, $10,080; Jan. 26, $10,450; Jan. 28, $7,950; Jan. 29, $21,650; Jan. 30, $2,890; Horn Silver, Jan. 30, $8,240; Lucky Cuss, Jan. 28, $2,000; Silver King, Jan. 26, 14,300 lbs., concentration; Eureka Con., Jan. 30, 48,845 lbs.; Richmond, Jan. 30, $19,063.72; Tombstone, Jan. 1 to Jan. 27, inclusive, $42,452.48; Stonewall Jackson, Jan. 1 to 24 inclusive, $20,469.21; Christie, Feb. 3, $7,867.

News in Brief.

GOUT is again troubling Beaconsfield.

PAUL DEVOUX, the Belgian politician, is dead.

YELLOW FEVER has broken out at several places in Brazil.

PIERRE ERNEST BERSOT, the French scientist and author, is dead.

ABBE DE BRAZE, in attempting to cross Africa, died at Ujiji.

THE deeth of Peul de Cassagnac's fathsr is announced from Peris.

COL. W. S. WATSON, civil enginesr, died at Marysville Saturday last.

BRUNEREAU, the notorious Colonel under ths Paris Commune, ie dead.

DURING the recent storm ovsr fivs inchss of snow fell at Tucson, A. T.

THE Moors at Fez, Morocco, rscently attecked the Jews, wounding several.

THE severest weather ever known in thet locality recently visited Sitka.

THE Indian Appropriation bill appropriates $219,533 less than last year.

A PARTY of eight robbsrs were recently killsd in Dakota by their pursuers.

JOHN LOCKE, Liberel member of Parliament for Southwark, Eng., is dead.

THE total coinage of the Unitsd States Mints during January was $9,576,500.

THE independence of Roumania has besn recognized by Holland and Greece.

THREE deaths occurred last week from starvation near Parsontown, Ireland.

AT Mount Weshington, Fridey last, the wind blew at the rate of 132 miles an hour.

THE Lsopold Cross hes been conferred upon Rosa Bonheur by the King of Bslgium.

THE investigation in connection with the colored exodus is proceeding at Washington.

LEON SAY has been elected President of the Finance Committee in the French Senate.

THE deeth of Sir Dominic John Corregan, the eminent Dublin physician, is ennounced.

FREEMAN, the Pocasset (Mass.) child murderer, has besn ordered to the insane asylum.

THE Western Iron Association et Pittshurg have advanced the price of iron to four cente.

THE trouble in the English cotton tradc continues, the operatives striking in severel localities.

THE French budget for 1881 estimates the expenditures for ths year at 2,773,391,473 francs.

THE railroad suit against Tilden and others has been virtually settled by a compromise of judgment.

THE menager of the Shepberd's Fold in New York has been indicted 25 times for ill-treating children.

THE first arrival at New York of colored people leaving the South reached that city Monday last.

A MONUMENT ie to be erected in commsmoration of Gen. Stark's victory over the British at Bennington, Vt.

Academy of Sciences.

The regular meeting of the California Academy of Sciences was held on Mondey evsning last, President Davidson in the chair. Messrs. A. T. Dewey and W. B. Ewer (of the MINING AND SCIENTIFIC PRESS) and Dr. J. B. Trembley were elected resident members.

Among the donations to the museum were some specimens of wild rice from Mr. Simpson, who had endeavored to maks it grow here in this Stats, but with no success.

Mr. Redding steted that, although Indien rice was originally found in the lakes of Wisconsin, and of the territory of the Northwest, it had been made to grow as far south in the Southern States as Arkensas, but that all efforts to make it grow in the California lakee had yet been uneuccessful. This was to be regretted, as one very valuable result of its growth was its irresistible attraction to all varieties of edible aquatic birds, which followed in great quantities its growth to localities where they had never before been known.

J. D. Stillman, of the University of California, read the result of a chemical analysie of the gum found on the *Torreya Mexicana*, commonly known from its odor as the creosote plant, sent from Arizona by Mr. Culbertson. The analysis proved the exudation on this plant, after the boring of it by a certain insect, to be essentially the same as that from which the stick lec, the gum lac, and the shellac of India, and one of the great sources of India'e wealth, is obtained. This creosote plant, called aleo grease-wood, growe abundantly in the lower part of Tulare valley and on the Mohave desert.

Mr. Redding and others, who know the plant, say that the exudation occurs only where the insects affect it, and this is chiefly in Arizona. The uses of the gum are various, and extend from those of wax for the wild flax-thread ueed by the Indians, to solder used by the Mexicans, and the cure of rheumatism for any person.

Mr. Stillman also read another interesting paper, ehowing the results of an analysis of the oil of the leaf of the California laurel or bay tree. He is pursuing still furthcr investigations with the oil, having found many interesting circumstances connected with it.

Dr. Behr read a paper on the gradual change of the flora of this peninsula, and on the supplanting of the native growths of all countries by those Africa and Europe, but of the latter particnlarly.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING JANUARY 6TH, 1880.

223,308.—WINDMILL—J. F. Barkor, S. F.
223,277.—LAWN SPRINKLER—C. Chamberlain, Santa Rosa, Cal.
223,279.—STRAW BURNING BOILER—H. K. Day, San Jose.
223,281.—ORE CRUSHER—P. C. DuBois, Copper City, Cal.
223,287.—SAFETY CLUTCH—B. E. Henriksen, S. F.
223,387.—KEYBOARD—C. C. Reynolds, Kelseyville, Cal.

FOR THE WEEK ENDING JANUARY 13TH, 1880.

223,581.—ROCK CRUSHER—E. Coleman, S. F.
223,529.—ROCK DRILLING MACHINE—H. Morse, S. F.
223,605.—SPARK CONTROLLING STACK FOR BOILERS—J. W. Pearce, Suisun, Cal.
223,543.—DRESSMAKERS' CHART—M. E. Riley, Harrisburg, Oregon.
223,554.—FLOUR-BOLT—A. J. Terry, S F.

FOR THE WEEK ENDING JANUARY 20TH, 1880.

9,048.—FEEDER FOR QUARTZ MILLS—T. A. Cocbrane, S. F. (reissue.)

FOR THE WEEK ENDING JANUARY 27TH, 1880.

223,875.—HORSE POWER—R. M. Beebee, Chico, Cal.
223,881.—SULKY PLOW—I. Burke, Sacramento, Cal.
223,800.—PLAITING MACHINE—J. E. Chenatte, Hillsborough, Ogn.
223,845.—DYNAMO-ELECTRIC MACHINE—S. D. Field, S. F.
223,804.—STEERING APPARATUS—J. Oates, Portland, Ogn.
223,913.—EXTRACTING METALS FROM ORES—O. Hofmann, Monitor, Cal.
223,922.—DUMP CAR—J. Jones, Lakevills, Cal.
223,819.—MITERING MACHINE—T. Schreppel, S. F.
223,823.—ORE STAMP—H. H. Taylor, Oakland, Cal.
225,964.—BAND SAWING MACHINE—O. M. Van Riper, Bodie, Cal.
223,825.—STEAM GENERATOR—J. B. Ward, S. F.
223,828.—KITCHEN TABLE—W. H. Wiester, S. F.
223,829.—COAL OIL STOVE—W. H. Wiester, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Petsnt Agency, ths following are worthy of special mention:

STRAW-BURNING BOILER FURNACE.—Harry K. Dey, Sen Jose, Cal.[1] Patented Jan. 6th, 1880. No. 223,279. This invention relates to certain improvements in the construction of furnacss for steam boilers, and is especially applicabls to that class of furnaces using straw as a fnel. It consists in the employment of a continuous horizontal and vertical grate, and, in combination therewith, of a horizontal plats at the rear end of the horizontal grate, by which the draft through the esh pit is prsvented from passing through the rear portion of ths grate to strike the flues directly, and is directed through the front part only. By this construction straw may bs burned in a fire-box boiler with good results. The straw, hsing fed into the furnace and ignited will bs consumed, and the oxygsn for its consumption is admitted only from the front, so that it must pass through the fuel and bscome heated before it reaches the combustion chember and flues. The verticel grats prevents the burned straw and cinders from heing carried against the tubes to clog them.

PNEUMATIC SAFETY CLUTCH FOR ELEVATORS. B. E. Henriksen, Thurlow block, corner Sntter and Kearny strsets, S. F. Patented Jen. 6, 1880. No. 223,287. This invention relates to certain improvements in elsvators and hoists of any description, such as ars employed to convey goods end passengers; and its object ie to eecure the cages or platforme of snch elevators or hoists against eudden fells, which are usually caused by the breaking of the cable or hoisting machinery. It consists in the employment of a pneumatio fan or plate in connection with the elevator platform or cage, and suitable mechanical devicee, whereby any unusual speed of the descending cage or platform will cause these devices to be actuated by the resistance of the atmosphere, and thus check or stop the speed of the platform.

ORE CRUSHER.—Pierre C. Du Bois, Copper City, Cal. Patented Jan. 6, 1880. No. 223,281. This device relates to certain improvements in that class of crushing apparatus in which the rock is broken by means of two jaws placed opposite to each other, one of which jaws is made to alternately approach to and recede from the other stationery jaw. It consiste in the novel combination of a breaking, grinding and sizing mechanism, in which the rock, ore or other material ie broken and pnlverizsd to any degree of fineness. This ie effected hy a peculiar arrangement and operation of a movable jaw with relation to an oppositely placed stationary jaw, and in certein mechanism by which thie jaw is operated.

WINDMILL.—John F. Barker, S. F. Patented Jan. 6, 1880. No. 223,308. The improvements consist in providing a frame which rotates in a horizontal plane, and which cerries on its arms a series of pivoted fans so arranged as to automatically present their edgee or faces to the wind during the revolution of the wheel, so that the wind-pressure will be exerted on one eide of the wheel, in combination with braces, rests and levers, whereby the action of the fans is automatically regulated.

OUR AGENTS.

Our Friends can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. L. Tharp—San Francisco.
B. W. Crowell—California.
A. C. Knox—Pacific Coast.

Every new subscriber who does not receive the paper, and every old subscriber not credited on the label, within two weeks after paying for this paper, should write persoually to the publishers without delay, to secure proper credit. This is necessary to protect ourselves and subscribers against the acts and mistakes of others.

Lakeport, Lake Co., Cal., Nov. 2d, 1878.

Messrs. Dewey & Co.—*Gentlemen:*—I hereby acknowledge receipt of patent, for which please accept my sincere thanks. When I have any further business in this line I shall certainly employ you. With kind regards, I am, Yours very truly, Chas. Slatterback.

Fresh attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

Bound Volumes of the Press.—We have a few sets of the back files of the Mining and Scientific Press which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce, and valuable for future reference and library use.

Sample Copies.—Occasionally we send copies of this paper to persone who we believe would be benefited by subscribing for it, or willing to assist us in extending its circulation. We call the attention of such to our prospectus and terms of subscription, and request that they circulate the copy sent.

Extra Copies can usually be had of each issue of this paper, if ordered early. Price, 10 cents, postpaid.

Geo. H. Powers	11	5	50 00

And in accordance with law and an order of the Board of Directors made on the 31st day of October, 1879, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the company, room 3, No. 220 Sansome street, San Francisco California, on Monday, the 22nd day of December, 1879 at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, togother with costs of advertising and expenses of sale.

L. L. DENNERY, Secretary.

Office, room 3, No. 220 Sansome St., San Francisco, Cal.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock of the Butte Hydraulic Mining Company is postponed to the Fifth day of January, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock is postponed to the second day of February, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

San Francisco, Cal., January 3d, 1879.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock is postponed to the Sixteenth day of February, 1880.

L. L. DENNERY, Secretary.

San Francisco, February 2nd, 1880.

Cataract and Wide West Gravel Mining

Company. Principal place of business, San Francisco, California. Location of works, Eho Mining District, Calaveras County, California

Notice is hereby given that at a meeting of the Board of Directors, held on the 2nd day of February, 1880, an assessment (No. 2) of Twenty-five cents (25 cts.) per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at 26½ Kearny street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 5th day of March, 1880, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 22nd day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. B. LAKE, Secretary.

Office, room 18, 26½ Kearny Street, San Francisco Cal.

Gila Silver Mining Company.—Location

of principal place of business, San Francisco, California. Location of works, Reveille Mining District, Nye County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of January, 1880, an assessment (No. 6) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, Safe Deposit building, 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Seventeenth day of February, 1880, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the Ninth (9th) day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. W. PARRISH, Secretary.

Office—Room 7, Safe Deposit Building, No. 328 Montgomery street, San Francisco California.

Rocky Point Mining Company.—Location

of principal place of business, San Francisco, California. Location of works, Placer County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the Fourteenth day of January, 1880, an assessment (No. 2) of Ten Cents per share was levied upon the capital stock of the corporation, payable immediately in U. S. Gold coin, to the Secretary, at the office of the Company, room 1, No. 314 Bush street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 20th day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Thursday, the 11th day of March, 1880, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors.

A. C. TAYLOR, Secretary pro tem.

Office, 314 Bush street, San Francisco, California.

Importers and Dealers in every description of

MACHINERY!

Sole Agents for the Pacific Coast for

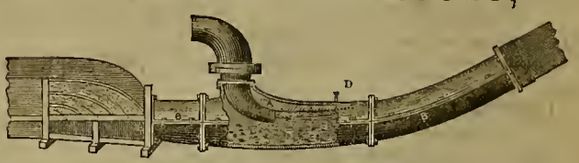
BUCKEYE

Engine Company.

J. A. Fay & Co.'s Wood-Working Machinery; Bement & Sons' Machinists' Tools; Blake Steam Pumps; Knowles Steam Pumps; N. Y Belting and Packing Co.'s Rubber Goods; Sturtevant Blowers and Exhaust Fan; Tuttle Co.'s Emery Wheels and Machinery; Payne's Vertical Engines and Boilers; Perry's Centrifugal Pump; Judson's Standard Governors; Dreyfus Self-Oilers; Gould Mfg Co.'s Hand and Power Pumps; Eclipse Windmills; Disston & Sons Circular Saws; Otto Silent Gas Engine; Dues' Elevator Cups; Ballard's Oak Tanned Belting.

Also on hand and for sale A FULL LINE OF MILL AND MINING SUPPLIES.

HYDRAULIC GRAVEL ELEVATORS,



For working flat gravel mines that have no dump.

Sluices gravel and water up hill on an angle of 45°, and will run any kind of gravel that will run in a flume. Handles rocks as easy as fine dirt, and will raise as much material as the water will carry off in a flume on 6 inches grade to 12 feet.

No bedrock cuts, tunnels or drains required. Machine a sufficient drain itself, and the process of mining the same as any other hydraulic mine. Is now a practical success in various places in California and Oregon. Send for descriptive circular to

JOSHUA HENDY,

No. 51 Fremont Street, Office of the Hydraulic Gravel Elevating Mining Co., S. F

SECURE PATENTS

Through Dewey & Co.'s **Scientific Press** Patent Agency.

Our U. S. and Foreign Patent Agency presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the Mining and Scientific Press. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free. DEWEY & CO., Patent Agents.

New Book on the Comstock.

The attention of MINING ENGINEERS and EXPERTS is called to the new work by John A. Church, E. M. Ph. D., on "The Comstock Lode, Its Formation and History." This very exhaustive treatise on this famous lode is fully illustrated with diagrams and colored charts showing sections, ore bodies, etc., and will be of great interest and permanent value for reference. Dewey & Co., Publishers of the Mining and Scientific Press, are sole agents for the sale of the work Mr. E. M. Sleator will act as their agent, and call on Mining Engineers and those interested in the great lode in this city with a copy of the book for their inspection.

Laura De F. Gordon, Attorney-at-Law, room 29, Montgomery Block, San Francisco.

Miners, write for your paper.

Kendall's Spavin Cure

Is a sure cure for spavin, splint, curb, callous, sprains, swellings, galls, lameness and all enlargements of the joints or limbs. It will completely remove a bone spavin without blistering or causing a sore. It is also as good for man as for beast, and is used full strength at all times of the year with perfect safety. A cure which we are knowing to is a person who suffered 15 years with hip-joint lameness and was permanently cured two years ago with Kendall's Spavin Cure. Remember we claim it will cure a bone spavin and completely remove the bunch without blistering.

Office U. S. Marshal, Western Dist. of Michigan, Kalamazoo, April 15th, 1879.

B. J. Kendall, Enosburgh Falls, Vt.—Dear Sir:—I received the two bottles of your spavin cure forwarded by express in January last. I am happy to state that it performed all your advertisement called for. In three weeks after I commenced using it the spavin was entirely removed and a valuable horse restored to usefulness. Very truly yours, John Parker.

Send for illustrated circular giving positive proof. Price, $1. All Druggists have it or can get it for you.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SAN FRANCISCO GOLD, SILVER, NICKEL AND COPPER PLATING WORKS,

Nos. 653 and 655 Mission Street, San Francisco, Cal.

EDWARD G. DENNISTON, - - - - - - - - - PROPRIETOR.

In consequence of spurious imitations of

LEA AND PERRINS' SAUCE,

which are calculated to deceive the Public, Lea and Perrins have adopted A NEW LABEL, bearing their Signature thus,

Lea & Perrins

which is placed on every bottle of WORCESTERSHIRE SAUCE, and without which none is genuine.

Ask for LEA & PERRINS' Sauce, and see Name on Wrapper, Label, Bottle and Stopper. Wholesale and for Export by the Proprietors, Worcester; Crosse and Blackwell, London, &c., &c.; and by Grocers and Oilmen throughout the World.

To be obtained of CROSS & CO., San Francisco.

SHEET IRON PIPE.

FRANCIS SMITH & CO.,

Manufacturers of

THE PATENT CHANNEL IRON WHEELBARROWS.

THE STRONGEST BARROW MADE. These Barrows are made by Superior Workmen, and of the best material. All sizes kept constantly on hand.

SHEET IRON PIPE.

Lap-Welded Pipe, all Sizes, from Three to Six Inches. Artesian Well Pipe. Also, Galvanized Iron Boilers, from 25 to 100 Gallons.

Iron Cut, Punched, and Formed for making Pipe on ground, where required. All kinds of Tools supplied for making Pipes. Estimates given when required. Are prepared for coating all size of Pipes with a composition of Coal Tar and Asphaltum.

Office and Manufactory, 130 Beale Street, San Francisco.

SHEET IRON PIPE.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 XX is the Strongest Explosive Known.
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

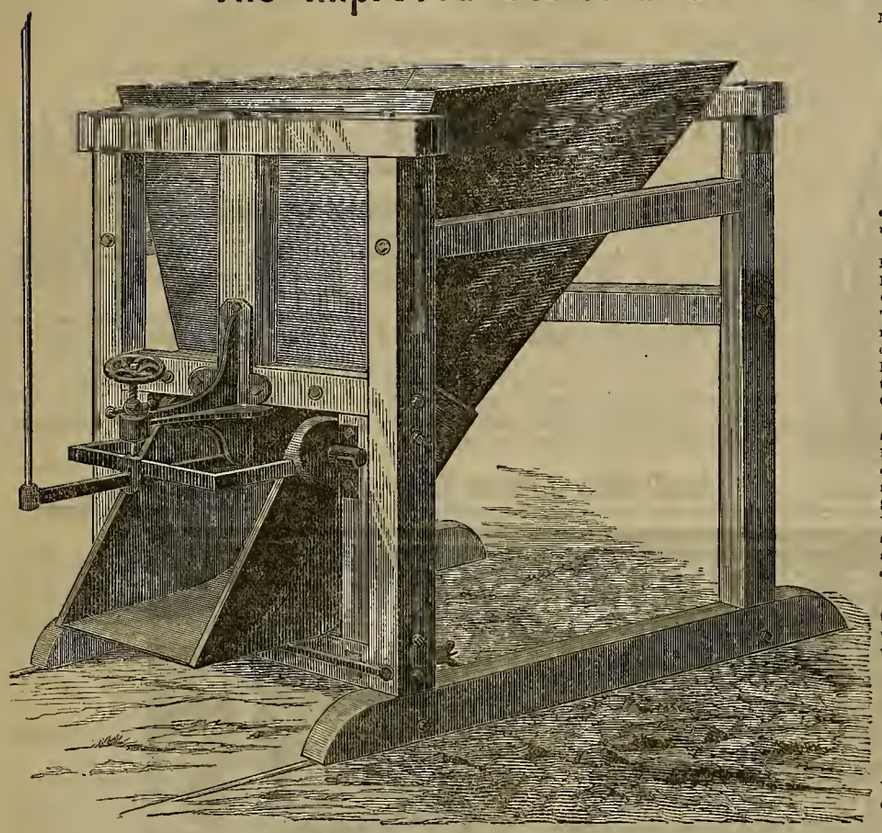
(Formerly McHaffie Direct Steel Castings Co.)

Works, CHESTER, Pa. 407 Library St., PHILADELPHIA

Price Reduced to $75.

NOW IS THE TIME TO BUY CHEAP ORE FEEDERS!

The Improved Stanford Ore Feeder,



Next best in the market to the famous

Challenge

ORE FEEDER,

Can now be bought for

$75 EACH!

It is in use in many mills on this coast, and wherever used gives great satisfaction.

The STANFORD and CHALLENGE Feeders, made by me, have superseded the Victor Ore Feeders, furnished by E. T. Steen, in the Alexander mill, J. B. Cooper, President, office, Safe Deposit Building, S. F. By special permission I am enabled to refer interested parties to Mr. Cooper.

In this connection I will state that I will give $50 to be shown up to this date one of the Eclipse Ore Feeders, manufactured by Prescott, Scott & Co., of the Union Iron Works, which is in general successful practical operation at any quartz mill on this coast.

I have made a specialty of manufacturing ORE FEEDERS, and know which will give satisfaction for steady work. This Improved

Stanford Feeder

Which I sell for

$75.00

Will beat any one in use—always excepting the CHALLENGE, which is

The Best of all.

JOSHUA HENDY,

Manufacturer of Hendy's Concentrator, Automatic Ore Feeders, Mining and Saw Mill Machinery, Etc.

VOLUME XL Number 7.

Electric Light.

American inventors are in the advance in discovering appliances by which electricity can be practically used for lighting, and the rapid progress made in this direction shows how indefatigable they are in such matters, and how capable they are to effect the purpose they have in view. They have ever evinced a wonderful degree of ingenuity in mechanical constructions, and their superiority has been acknowledged throughout the world by the readiness with which their inventions are adopted. It is truly said that "A prophet is not without honor, save in his own country," and the same axiom might be justly applied to new inventions.

In England and in Europe they are far ahead of our own people in applying our inventions to their own benefit. There are already three points on the English coast where the electric light is used in lighthouses. Two lighthouses are using it in France, and Russia has one at Odessa, and with all the progress already made in electric illumination, the United States have not yet placed it in any lighthouse.

In England, at Charing Cross, a 20-horse engine sustains 60 electric lights, of which 10 are at the Victoria station of the District railway, 40 on the banks of the Thames, and 10 on Waterloo bridge. There is a distance of over two and a half miles between their extreme points. The longest radius from the electric engine is a mile and a half, and this with the number of lights in proportion to the power of the engine, demonstrates that previous calculations as to the capability of this method of lighting have been greatly below what they should be.

The electric light has been recently introduced into some of the mines on this coast with very favorable results. It has given full satisfaction in one of the leading gravel claims in Nevada county, in this State. Now that a commencement has been made in its application to our mines, and also in a moderate degree in the illumination of some of our public buildings, we hope that we will soon outstrip our European brethren in putting into use this valuable light.

At the Free library in this city they are using three electric burners, which give a strong, white light sufficient to illuminate the large room, and at a cost of about one-third of the gas heretofore used, with a far greater volume of light. The cost would be still less if the charges for light were confined to the actual time it is used; the Electric Light Co. charges for the whole time that the electricity is generated. The lamps are used from about 5 P. M. to 9:30 P. M., and the company charge the library for them until 12 midnight, which is two and one-half hours in which they are not used.

Double Reel Compound Geared Hoist.

The engraving on this page represents the compound geared mining hoist, with inclined engines, and double reels for flat rope, of a type manufactured by Prescott, Scott & Co., of the Union Iron Works in this city.

It is specially designed for sinking rapidly to great depths, and for working in the pump shaft, when the permanent hoisting machinery for raising the ore has been erected.

By shifting the lower intermediate shaft, the extra gears are brought into action, and the power multiplied. In case of accident to the regular hoisting machinery, one compartment can still be utilized by attaching the rope with its cages to the extra reel of the pump hoist, until such time as the repairs are effected. The Union Works are prepared to furnish with dispatch these machines with 16-inch cylinders, 24-inch stroke, three sizes of wheels and four sizes of pinions; or 18-inch cylinders, 24-inch stroke with three sizes of wheels and four sizes of pinions. The reels are 36 and 40-inch.

ADOLPH BORIE, ex-Secretary of the Navy, died recently at Philadelphia.

Advantages of Incorporations to Mining.

In the combination of men to develop and work mines they generally act under incorporated organizations. This is done to facilitate the transfer of individual rights in the property. These rights are represented by shares of stock, which can be disposed of with the same readiness as an other personal property. It also relieves the holders from the personal responsibility which would be imposed upon them under a copartnership. The supervision and management of the mines is left to officials who are appointed by the board of directors, and there is no requirement for the individual to act in the matter.

Under a partnership, if one of the partners should be dissatisfied with the arrangement, or should wish from any other cause to cease his connection with the enterprise, he might find it impossible to do so. He might not be able to dispose of his interest, or he might not be able to accomplish a settlement of it with the remaining partners. Even if he preferred remaining in the partnership, he might be involved in pecuniary embarrassment by the action of his associates, who could against his remonstrances incur indebtedness which he might be unable to cancel. If he possessed ample means, he might be ruined by the dishonesty of one or more of the members of the firm. The responsibilities attendant upon a copartnership are numerous, and might prove to be annoying and burdensome. All these difficulties he would avoid under an incorporated action. He would be free to remain in, or to leave the concern at any time.

The chief advantage of an incorporation is that sufficient capital can be obtained for the prosecution of the full working of the mine by the aggregation of moderate sums derived from the sale of small lots of stock. This aggregation will come from the many, and the investors who are willing to place their small amounts in the enterprise, would not, and could not, advance larger amounts. If the mining interest had to depend for its vitality upon the action of individual or partnership operations, it could never have assumed the prominence which it now holds as a great national industry. It would have been confined in its efforts to a very limited channel. It would have been almost unknown, and but seldom heard of. Its present wondrous success would not have been attained. The impulse given by it to so many attendant industries would have been unfelt, and the widespread prosperity which it has conferred upon the world would never have existed.

The man who first conceived and put into operation the idea of incorporated bodies, was a public benefactor; and could his name now be known, his memory should be held in especial veneration. It is by this combined action that the industries of the world have been advanced, and are still kept in motion. There is no industry that owes so much to incorporation as does that of mining; it has been fostered and sustained by it; to it, it owes its existence; without it, its rich fruits would never have been produced.

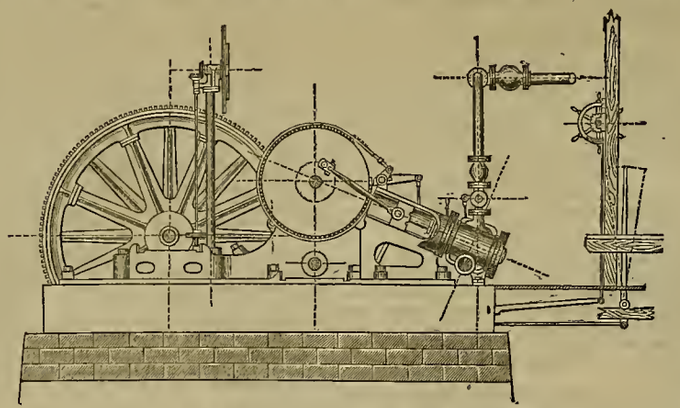
The U. S. Fish Commission on the Pacific Coast.

Prof. David Star Jordan, Assistant U. S. Fish Commissioner and in charge of the investigations into the fish and fisheries of the Pacific coast, U. S. A., the results of which will be incorporated with the census of 1880, has lately paid this city a flying visit.

Prof. Jordan is one of the best known and most accomplished ichthyologists of the United States, and a most persevering and thorough worker. He has probably done more than any other man living to increase our knowledge of the fresh-water fishes of the country, and there is no doubt that his labors upon this coast will result in the accumulation of a vast number of fresh facts, of economic as well as of scientific interest, about the habits, geographical distribution, variations and value to mankind of the as yet only imperfectly known fish-fauna of our shores.

He is accompanied by his pupil and secretary, Mr. Gilbert, a young man who has already made his mark in ichthyology.

Prof. Jordan and Mr. Gilbert commenced their work at San Diego, where the weather is more favorable for procuring specimens than it is here, and are gradually working their way up the coast to San Francisco, where they will arrive in April or May, and will probably make that city their headquarters for two months or thereabout.



DOUBLE REEL COMPOUND GEARED HOIST.

Altogether they will spend nine months upon the coast. During the two days of their visit, a considerable quantity of fishes were purchased in our markets, to be packed in ice and sent in a fresh condition to the Smithsonian Institution, where life-size casts will be taken, and colored so as to become an exact fac-simile of the living fish.

Prof. Baird, writing some time ago, stated that 600 of these casts had already been taken, and our State Fish Commissioner, Mr. B. B. Redding, who has lately paid a visit to Washington, speaks in glowing terms of their accuracy and beauty.

This is the only method by which the exact form and true coloration of a fish can be preserved for examination, as alcohol destroys or changes the colors and more or less shrivels and contracts the tissues, and a skin cannot be relied on for color or shape.

The Fish Commission desire to obtain at least 50 specimens of every species inhabiting the west coast of the United States, so as to have a series sufficiently large to show all variations due to age, sex or habitat. The greater portion of these will be preserved in alcohol for anatomical examination; but, if the first attempt to transmit fresh fishes in ice across the continent proves successful, the experiment will be repeated with examples of other species, as it is the desire of Prof. Baird to enrich the National Museum with casts of every form found in the waters of the United States.

Catalogue of the Pacific Coast Fungi.

Previous to the year 1876 nothing had been accomplished in the study of the fungi of this coast, with the exception of a few species collected by the Wilkes expedition, which were at that time referred to Professor Torrey for identification. But four or five of these were determined and of these but one or two can now be traced. Since that period, although the flowering plants have been most thoroughly studied, the fungi of this coast have been entirely neglected.

Fully realizing the importance of the undertaking, not only for its scientific value, but also from an economic standpoint, Dr. H. W. Harkness, of this city, and Justin P. Moors, of San Rafael, some four years since determined to devote their leisure to making a collection of the Pacific Coast fungi. These gentlemen have now published, under the auspices of the California Academy of Sciences, a catalogue, of which we have seen the proof-sheets. The list is the first of the kind ever published on this coast, and will be of great service, no doubt inciting many others to a study of this most interesting department of botanical research.

The authors do not claim that the catalogue contains anything like a full list of the fungi of this coast, or even of their own collection. It is merely a catalogue such as they know to be found here, and such as they have fully determined. A large mass of material still remains in their hands for study and determination, as leisure will allow. In the cave fungi, or fungi of our mines, comparatively little has been done. Want of literature on this subject has been a great hindrance to them in their work.

While they have not been able to visit every portion of the coast, a glance at the catalogue will show that their explorations have extended over quite a wide range of territory—from Mt. Shasta on the north to Fort Yuma on the south—from the seashore to the eastern limits of the Sierras.

In reference to the geographical distribution of the fungi, it is noted that most of our species found upon the low lands are common to both Europe and America, whilst of those growing along the Sierras, many are the same as the Alpine species of Europe; others are peculiar to our own coast. Again, it will be seen that the hot and arid desert at the south yields species common to Africa. The distribution, the authors have aimed to make clear by giving in every instance the locality where found. They have, in the case of the Hymenomycetes and other edible fungi, indicated the fact by appending an *E.* They have also added the habitat of our *parasitic fungi*, to aid the student, and have indicated the *new species.*

Messrs. Harkness and Moore have brought a great deal of intelligent labor to bear on their task. Both gentlemen are enthusiasts in their specialty, and the result of their work is a credit to themselves and the society under whose auspices the catalogue is published. They have followed in the first part the arrangement of the genera as given by Fries, in his Hymenomycetes Europæi. For the rest they have adopted the order, as far as practicable, as given in Cook's Hand-book.

MINING IN ARIZONA.—From a private letter from Tucson we take the following items of interest concerning mining matters in the Territory: Mining excitement is beginning to run high. Some of the most noted experts on the coast are here examining properties, among whom I notice Geo. Hearst, Taylor, Hoffman Farrish and others. Many properties are changing hands at satisfactory figures. New and rich districts are constantly coming to the front. Among the most noted of these is the district in the Dragoon mountains, where Gen. J. B. Allen is opening the Silver Cloud—a rich bonanza of chlorides—and the Empire mining district, where the celebrated prospectors, Hank Williams, Toppy Johnson and Capt. Weeks, are discovering and locating rich prospects, which will soon be developed into paying mines. This latter district is only 40 miles from Tucson, with a good road all the way. The railroad has made an advance of 12 miles towards us from Casa Grande.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Wiegand's Amalgam Refining.

A Method Simpler, Cheaper and More Complete Even Than That of Prof. Riotte.

EDITORS MINING AND SCIENTIFIC PRESS—Sirs: The highly interesting communication of Prof. E. N. Riotte, relative to the refining of copper-base and of lead-base amalgam, which communication appeared in your issue of Dec. 20, 1879, induces me to break the silence which hitherto I have kept respecting a method of reaching not only the very same results which he recites, but besides, of attaining valuable points which his method does not; for my method is simpler, more effective and far cheaper. I sincerely hope that Prof. Riotte's stoichiometric formulæ may not cause many practical millmen and mining managers to look upon his communication with a distrust which it does not merit.

History of Amalgam Refining.

So far as I have been able to learn, my own are the earliest methodic, practical investigations prosecuted on a working scale, of the now solved problem of amalgam refining, and within that field there still remains room for great discoveries, and more than one fortune to a radical investigator favored by capital willing to sink a portion of itself in working experiments.

I, myself, undertook the task at first, on the score of curiosity and friendship, but finding that experimenting was a very costly luxury which few of those who would be most aided by it would pay for, I sought to patent my discoveries and inventions that I might be able to *exact* what was *freely* accorded only by a few.

I therefore resolved to determine *what economies are possible within the doors of the producing mill*, by means of which the producers of base amalgam (the common result of heavy treatment with bluestone) might escape the prodigious discounts on the sale of bullion, which more than any single influence has ruined the enterprising men who sought to snatch from the *wastes* of our mills and mines, the millions annually sunk in our inland river beds, whose waters never reach the sea. But of course the *origin* of copper or lead in amalgam, whether from the native ore or from mill "treatment," makes no difference either as to the *necessity* for refining it cheaply, or as to the adaptation of my process to that end.

Early Producers of Copper-base Amalgam near Virginia.

I was incited thereto as early as 1866 (I think; my earliest notes thereon being destroyed by fire, I am uncertain) by the destructive discounts which overtook Louis Janin, Esq. (Canyon mill, now known as Parke's Express mill), of Virginia; and later, by Messrs. F. Birdsall & Co., of Dayton (whose works are now incorporated as those of the Lyon Mill & Mining Company), and by Messrs. Likens & Bullion and Jno. Briggs (also near Dayton), and by Messrs. Parke & Bowie, of the Railroad and Express mills of Virginia, and by the Carson Valley Mill Company, near Sutro.

The foregoing parties were then the chief producers of copper-base amalgam in this vicinity, just as Fair & Mackey (our Bonanza kings) now are. And being patrone of my assaying establishment, *their* interests became *indirect* interests of my own.

Chief Difficulty Overcome, and a Chance for Safe Investment Remaining.

Like Prof. Riotte, in my investigations I very early encountered the confueing problem of eliminating *both* lead and copper from silver amalgam. Hot mercurial leaching would readily (though with poor results) separate the lead from the silver, for the simple reason that, *as compared with silver*, lead is far more fully soluble in hot mercury than silver is; but the copper remained, at first staggering me as it had all prior students of the problem *by that resort*.

While prosecuting those investigations, besides touching facts which Prof. Riotte recites, I obtained some very valuable results relating to refining lead-base amalgam, which, when further developed, I purpose patenting. And I also obtained the *cue* to the process (patented in 1873) for separating silver by leaching it away from the amalgams of *other* metals than lead, which of course covers the separation of silver from gold, as well as from any other metal, and secures me time in which to develop that most important and interesting chapter of "parting" the precious metals mercurially.

One thing, however, became boldly plain to me as soon as I confined my attention to the problem of *either* removing the copper from the silver (as Riotte did) or of removing the silver from the copper and gold, viz: That it is on *amalgam* and *not* on melted or retorted bullion that the economy of *mechanical* refining or parting became possible.

The separation of the silver from both gold and copper in base amalgams at length I perfectly accomplish, *and in a large, cheap, working way*, just as I then did in a laboratorial *miniature* way.

A Success that Impoverished the Inventor.

In 1873 I patented my method, and then my poverty began. It took all I could earn and filch from regular business—perhaps more justly due to generous creditors—to perfect and simplify the method and apparatus to a point where Stupidity itself must see that there's "Millions in it" *for those who use it*, and small share of their savings for me.

A Plan for Cleansing Quicksilver and Amalgam from Lead.

One method of eliminating the lead from a complex mixture of amalgams, not being patentable, I see no reason for withholding; especially as it so closely resembles Prof. Riotte's, but is only cheaper.

It is chiefly valuable, however, as a step *precedent* to my own patented system of *copper*-base refining; and if any patent agent can get me a patent for it in *combination* with my process, I shall be only too glad to pay him a liberal fee. It is as follows:

The mechanical agitation or trituration of lead-fouled quicksilver or amalgam (whether copper-base or not) *with bluestone* (sulphate of copper), but *not* as Mr. Riotte commends, with *salt*, but WITHOUT salt.

Those of your readers who are not chemists will not care to see the reactions indicated by symbols; those who are do not need it—a moment's reflection must make them apparent. It is sufficient to say, that practically they cause copper to *expel* lead (as sulphate of lead), replacing the lead by copper in the amalgam (and so far as my limited experiments on this point go to show, with absolutely *no* loss of either gold, silver or mercury), giving me a very simple *form* of amalgam to operate on, viz., goldo-copper-silver amalgam only, from which, by my process patented in 1873 (or by another patented later), I can *completely* separate the silver*, leaving the gold and copper only in mixture, and in such a physical condition after retorting as to be readily oxidized atmospherically, and ready for solution in even the weakest "Chamber" sulphuric acid—indeed, that acid needing dilution with water.

The Chief Gain.

But the crowning fact in relation to my process is, that while its by-product (CELLULAR COPPER SPONGE) makes the most perfect bluestone which it is possible to produce, INCIDENTALLY it effects the *liberation of the gold in the bottom of the bluestone dissolving vats.*

This, of course, abolishes absolutely *all* discount on the gold *part* of the bullion which formerly *was* discounted on sale quite as much as the silver, and *averages* discount on the product of a mill to the very lowest point possible, so long as silver is not coinable without restriction for all owners into all the dollars it will make, as it is the *right* of all silver producers to have done for them by the Government, mono-metallic goldites in financial creed to the contrary notwithstanding.

The Cheapness of It.

When the restoration of the metallic copper to the form of bluestone† is considered as a part of one of my processes, the costs of the operation are literally LESS THAN NOTHING, for the bluestone (or to a certain extent the metallic copper) becomes a source of profit, under the terms of the licenses which we issue.

A Caution.

Do not understand me as commending the foregoing method of *lead* elimination from amalgam as the *best*, even if it is both simple and apprehensible. But in my judgment it *is* far better as a process than the mercurial leaching process once practiced (I am told) at Pioche. At a future time I hope to submit to your readers a lead-base process of greater merit than either, but until further experiments, now in course are completed and the results patented, I deem it best to maintain silence in relation thereto.

A Fair Rich Man May Get Richer Safely.

It is proper in closing this long letter, also to inform you, that you may the public—that for a long time I have been studying up and preparing a system of parting (separating) gold from silver in amalgam which is *free* from base metals of all kinds whatsoever; and that I am embarrassed and delayed in this undertaking chiefly by inability to get capital, *safe to trust.*

I greatly need funds for some costly experiments; and only with a party whom I *know* to be as simple in spirit as I am myself, and as honorable as he may be rich, and ready to sink a few thousand dollars, and still be happy in his faith in me and in my ultimate results, or else in my eventual re-payments of outlays—only with such a party am I willing to make business relations on this matter. But with such an one I am confident that I can do well, while enriching him. Do you *know* of such a rare person?

The Process in Extensive Use.

The "success" of my process, perhaps is best presumptively attested by the fact that our bonanza kings (after a very cautious trial at the Omega mill), have put it in at all their large mills when running the base method of amalgamation.

At the cost of the wages of one man and little steam for heating, 4,000 lbs. of amalgam, however base, can be perfectly stripped of its silver; and the silver got out will be coin fine, or over; and it is an important fact to know that the refining operations are not attended with any loss of either mercury or silver.

How about loss of gold?

Carelessly operated some gold may be lost; but at the Hoosier State mill, where I have the personal management of the refining, I am producing coin-fine silver from amalgam 160 fine; and I do so without *any* loss of either gold, silver, or quicksilver, while at the same time both the gold and silver produced are absolutely free from lead. Very respectfully,

CONRAD WIEGAND.

*And when the alloy is pure tough copper only (while no gold is contained), silver, coin-fine, mints (or can be minted) *exempt from all charges*, except a nominal one for melting and assaying, just as if it were 1,000 fine.

†For *nascent* subchloride of copper seems far more effective for work in an amalgamating pan than prepared Cu Cl, and the mixture of *bluestone and salt* IN THE PAN, in practice, is found to work better than when copper chloride is leached out, as indicated by Prof. Riotte, for renowned use.

The Alkalinity of Tulare Lake Water.

EDITORS PRESS:—I have received a letter from a resident in the San Joaquin valley, asking if the sample of water from Tulare which was analyzed in the University laboratory was not taken from a hole near the shore, and therefore was not representative of the body of the lake. He states that those who have gone out in boats say that the central lake has palatable water. He mentions that fine trout live in the water, water birds frequent it, and that turtles are shipped thence to San Francisco; also that in places where the lake water was driven by last winter's storms upon the grain sown along the shores, the crop was benefited rather than injured. These things he says would not be so if the water was alkaline like Owen's or Mono lake.

In the latter conclusion my correspondent is right, and, therefore, I wish to correct the impression in regard to the *degree* of alkalinity involved in my statement of the composition of the water of Tulare lake. It does not in any manner approach the alkali lakes he speaks of. It does not imply that fish, fowl and other tolerably adaptable live things cannot safely live in or on the water where it is as strong as stated. It does not even imply that crops irrigated with it may not make a healthy growth, *so long as the water is not allowed to evaporate on the ground to any great extent*, especially if the carbonates should be neutralized by gypsum, but it *does* imply, that irrigation as ordinarily practiced now, giving just as much water as is needed for the crop, and not enough, nor in such manner as to wash it through and thus relieve the soil of the accumulated salts, would in a few (in some cases in one) years render the soil both unproductive and untillable.

Now as to the suggestion in regard to the possible exceptional quality of the water analyzed, I am informed by Mr. Thomason that the sample analyzed is from no bay or inlet, but from the plain body of the lake. Its basin is not cut up by islands to any serious extent; and thus, according to the well-known laws of diffusion, and in view of the stormy season, causing as is said flood-tides on the lee shores, it is difficult to conceive how there could be any serious difference in the general body of the lake, unless at the month of Kern river, locally. I say *serious* difference, for some there would be, but unfortunately not enough to affect the general conclusion. There is but one hypothesis that could account for local alkalinity in such a body of water, and that is, the possible existence of alkaline springs. There is no reason to suppose that such exist, and in fact the reverse is the case, in view of the geological structure of the country. But still it is possible, and in view of the capital importance of the subject it should be investigated, and that at once. I have invited my correspondent to help to obtain the necessary samples of unquestionable authenticity. Not less than two gallons should be taken, in perfectly clean vessels, glass if possible; but a water keg, or a well cleansed jug will do. Ship by freight or express to me. It is no small question, and I should welcome any help to bring it to a prompt decision.

Smelting and Reduction Works in Utah.

Utah has the following smelting and reduction works:

Districts	Mills.	Stamps.	Furnaces.
Alta	..	..	..
Beaver	1	20	..
Bingham	3	40	..
Camp Floyd	1	20	1
Frisco	..	..	..
Honansville	1	10	..
Ophir	1	10	..
Park	3	80	4
Silver Reef	5	38	..
Stockton	1	15	..
Tintic	3	52	..
Total	19	235	5

Of smelting works proper there are in the valleys of the Cottonwood and Jordan, and two miles from the city, the following:

Name.	Stacks.
Old Telegraph Works	5
The Mingo	4
The Germania	3
C. W. Schofield & Co	2
Morgan & Pittsburg M. & M. Co	1
Total	15

Elsewhere in the Territory are the following customs smelters:

Name.	Stacks.
At Frisco, the Frisco Smelting Works	2
Godbe & Co	1
Cullen, Campbell & Co	1
At Stockton	2
At Rush Lake	2
Total	8

Of these 23 stacks probably not over one-half are now kept steadily employed. Leaching works, using Kustel's process, have been established at several points, the largest plane being used by the Old Telegraph company.—*Silver Reef Miner.*

The Mines of Utah.

Ten years ago, on the 12th of January, Woodhull Bros., of Salt Lake City, shipped the first carload of ore from mines in this Territory over the Utah Central railroad. At that date Colorado had been producing ore ten years, Montana eight years, Idaho six years, New Mexico and Arizona five years, Oregon and Washington Territory six years.

Ten years have elapsed—years, for the most part, of general stagnation and depression in business in this country, in which all of the leading industrial interests of the nation have been more or less crippled. Capital, so largely needed in the equipment and development of mines, has timidly sought its hiding places and nestled in bank vaults, or been invested in Government bonds and other evidences of debt. In face of all these difficulties, supplemented by local embarrassments growing out of sensational rumors affecting the security of person and property, and by a well-founded fear of hostile legislation on the part of the dominant religio-political party of the Territory, the mining industry has struggled to the front, and Utah now stands fourth on the list of mineral States and Territories in the Union. Within the short period of ten years this great interest has leaped from helpless infancy to lusty manhood. Its aggregate production amounts to nearly $47,000,000, with an annual average yield of $4,700,000, or nearly 10% on an investment of $50,000,000.

Taking the last named sum as a fair estimate of capital and labor actually invested in Utah mines, mills, smelters, and all the appliances and adjuncts of mining—and we think it will fully cover all expenditures—how stands the case to-day? We place the actual value of all the mines, prospects, mills, smelters, sampling works, machinery, tramways, etc., in Utah, at double the supposed actual investment, or $100,000,000 (and well-informed mining men will, we think, sustain us in this estimate), and capital invested here during these 10 exceptional years has doubled in value, besides paying nearly 10% per annum on its original investment. We believe the facts would show a much larger return.

These are the direct results; it is more difficult to sum up the indirect, but equally substantial benefits, accruing to all classes and to the Territory at large through the development of our mines. In a material sense our mining industry furnishes life-blood to the body politic. Within the period we have referred to, it has lifted Utah from poverty and isolation to wealth and influence; has helped to build and largely sustain her railroads, furnishing four-fifths of their income; has erected churches, established schools, hospitals and charitable institutions; has infused into an unenterprising people elements of activity and progress, and added to the population a class of people that any community may well be proud of.

Close up the mines, silence the clangor of stamps, put out the fires of smelters, and Utah would revert to the obscurity and insignificance of a cabbage garden.—*Silver Reef Miner, Jan. 10th.*

Leadville's Ore Output.

According to the weekly circular of Uthoff, Van Zendt & Co., ore and bullion brokers, the present daily output of ore from Leadville mines is as follows:

Mines.	Tons.	Mines.	Tons.
Chrysolite	125	Iron Mine	25
Little Pittsburg	150	Smuggler	5
Little Chief	50	Tucson	5
Dunkin	15	Silver Wave	10
R. E. Lee	35	Little Ella	5
Climax	20	Highland Chief	30
Carbonate	35	Argentine	10
Yankee Doodle	5	Little Giant	15
Morning Star	40	Oro La Plata	20
Colorado Prince	5	Scooper	10
Nevada	5	Miner Boy	5
Crescent & Etna	5	Double Decker	3
Long & Derry	5	Others	35
Pendery & Glass	5		
Forsaken	20	Total tons	698
Agassiz	5		

COPPER IN ARIZONA.—To the north of Prescott, in the Black hills, there exists a section of country that contains some of the most wonderful copper ledges ever discovered in the United States, not excepting those of Lake Superior. After being mammoth in dimensions, they carry on the surface, before the richest ore is reached, ore that assays from 33% to 50% in pure metallic copper. The mine owned by Col. Biddle assays, from average ore, 47½%; while that belonging to Hugh Richards and Col. C. P. Head reaches nearly 60%, with a fair quantity of silver. Railroad communication heretofore has been remote, transportation high, rendering it almost impossible to handle any mining property which was not about all metal. But now that a remedy is coming to us, these wonderful properties are stepping to the front, and we hope soon to chronicle the sale of two or three copper mines in the near vicinity of Prescott for what they are worth, and that means millions.—*Arizona Miner.*

Mechanical Progress.

Iron in Bridge Building.

The use of iron in hridge constructiou has produced a boldness of conception in the presnt generation of engineers which casts the performances of their prsdeoessors entirely in ths shade. A half century ago such spans as ths fallen ones of the St. Charles and Tay hridges, for the loads that they wero calculated to support, wore impossible. Now thsy are far from heing of the first magnitude. There aro 10 truss bridges across the Mississippi ahove St. Louis, which are not regarded as very wondsrful structnres, and yet seven of them have spane as long as those of the Tay hridge.

The hridges at Winona, LaCroese, Dubnque, Keokuk and Hannibal, have spans of 240, that at Rock Island of 250, and that at Louisiana of 256 feet. The span which gave wsy at St. Charles was 320 feet in length, yet the same bridge hae two spans 406 feet long. Over the samo river is a truss hridge at Leavenworth, with threo spans of 340 feet, and another at Glasgow with fivo of 315 feet. Acroes the Ohio thero is a trnss hridge at Steuhenville with a span of 320 feet, one at Parkershurg of 350, one at Cincinnati with a span of 515 fest, the longest truss yet hnilt, and one at Lonisville with a span of 400 feet. The truss bridge over the Kentucky river, on the Cincinnati and Southern railroad, has three spans 375 feet in length, resting on iron piers 175 feet high. The proposed hridge over the Hudson at Poughkeepeie has five spane of 500 feet with piers 135 feet above high water.

In Europe there is a truse hridge over the Vistula at Graudenz with 12 spans of 300 fset. The truss hridge of Lessart, in France, has a span of 314 feet, and was pushed acrose from one ahutment to ths other after being put together. The hridge over the Rhine at Wesel, has four spans of 313 feet. The Kulenhurg bridge in Holland, which was the monarch truss before the constrnction of the Cincinuati hridge, has a span of 492 feet.

From these examples it would eeem that the St. Charles and Tay hridges, instead of heing risky engineering ventures, are entirely within the domain of expsrience. But, nevertheless, ths fact remains that, notwithstanding ths boldness with which the engineers of the present day meet the exactions of the locomotivo, they ars comparatively novicee in the use of iron. The first iron bridges wsre of cast-iron, and soon proved to he too lightly proportioned. The first suspension hridges were similarly defective. Does it remain to hs proved that the wrought-iron work of the past 20 years hetrays too great a confidence in the material? Were the St. Charlee and Tay disasters unaccountahle accidents, or were they fair tests of current engineering theories? These are questions which engineers would do well to discuss.—*St. Louis Globe.*

Why Does Steel Harden?—Mr. James Nasmyth opens up a very interesting question in the following letter recently published in *Engineering:* "In these days of earnest scientific investigation, it is to me a matter of surprise that no special attention has been given to one of the most vitally important subjects, namely, 'the reason why' steel hecomes hard on heing suddenly cooled down from a red heat by plunging it into cold water. On this one simple hut wonderful property of stssl depends the entire range of those mechanical arts which lie at the hasis of civilization, and hy whose exercise we are enahled to rise above the savage condition. It occurs to me that it is from the want of due consideration of the enormously important consequences that arise from this wonderful, yet simple, property of steel, that the causee of so remarkable a change as respects hardness which results on suddenly cooling it from a red-heat condition, has prevented the subject from receiving special attempts to investigate its nature. While in these daye the most powerful and active intellects are occnpied in physical investigations, in searching into the nature of those actions in matters which are ever in progress around us, so far as I am aware no one has made an attempt to enter npon this vitally important subject. It is in the hope that these remarks may chance to direct the attention of some one who may have the ahility and opportunity to enter upon the investigation to do so.

Cracking in Hardening.—In tools composed partly of iron and partly of steel, steel laid as it is called, the tendency to crack in hardening may he avoided in a great degree hy hammer-stretching, hammering the steel edge at a low temperature until it is expanded, eo that when cooled in hardening it will merely contract to a state of rest with regard to the iron parts; the same effect can he produced hy curving a piece, giving convexity to the steel side hefore hardening.

Immense Wagons.—Three immense wagons to be used in the mines of Colorado are heing made in Chicago. The hack wheels are six feet three inches in diameter and the tire is five inches wide. The wagons, including box, are nine feet high. They are each to he drawn by twenty yoke of oxen, and are capable of carrying ten tons each.

Improvements in Boiler Making. — Ws made reference a few weeks since to some improvements in boiler making, whereby ths leakags due to ths unequal expansion arising from the difference of temperature between the top and hottom of a boiler might be avoided. The remedy consisted in welding the plates in complete rings, se as to avoid the necessity of rivet joints at the bottem of the hoiler. This plan requirsd the rolling, for some boilers, of much largersheets than had hithsrno been attempted. That difficulty, however, was soon overcoms, when a second pressnted itself, in bending such lsrgs plates into the proper "sst." This work, according to the Newcastle (Eng.) *Chronicle,* entailed the expenditure of a largs amouut of additional time and labor. At length, however, tho managing engineer of the Jarrow Rolling Mills of Nswcastle couceived the idea of using vertieal "bending rolls," instead of the ordinary horizontal ones. The thought was promptly developed and a set of the new rolls erected at the Jarrow Works, which the *Chronicle* says are exceedingly eimple in arrangement and eminently successful in operation. By their use there is a large eaving of the labor and time consnmed in the ordinary course of plate bending; and what is of equally valuahlo importance, the required "set" of the plato is ohtained to a nicety, and with perfect ease. By the introduction of these improvements, those works are now onahled to construct marine boilers of extra large size; and the experiment has been completely euccessful.

Do not Burn Your Tires in Welding.—A correspondent of the *Wheelwright and Blacksmith* writes under the ahove head as followe: I would like to call the attention of carriags smiths to a great evil that many fall into when welding tires, viz.: of allowing the tire to burn on each side of the lap while taking a heat. Many smiths fail to take into consideration the fact that it is impossihle to heat a piece of iron two inches thick, especially when it is formed of two piecee of equal thickness, one placed upon the other, as quickly as one of half the thickness could he heated, and hence, having lapped their tire, the full force of the hlast is throwu upon it. As a result, the tire is put into service with a weakness at each side of the weld, caused hy being hurnt while the weld was heing hrought to the required heat. That there is not a particle of need for such carelessness every smith knows, no matter how poor a workman he may he. Give your weld a gradual heat; attend to it yourself, and not throw the responsihility upon your helper. Have a clsan lot of coal and under all a clean fire, and you will never lose a good customer hy having him discover a rotten place in hie tirs, causing it to hreak when far from a forge.

After Coal, What?—At the last meeting of the Liverpool Eginesring Society, a paper was read touching the prohahle exhaustion of coal, in which the author advocated the substitution of the tides as a producer of motion which would outrival all other sources of mechanical power. A correspondent of ths *Builder,* too, is of the same opinion. A compressed air chamher filled hy the tide at Brighton, for instance, would, he is confident, run an atmospheric railway, such as Brunel invented, from that place to London. If the tides could he thus utilized, all our railways and factories, in fact, all the work now done hy the steam engine, could he performed by them. There would, moreover, he no jerk, no steam, no smoke, no noise. Apart from the fact that the present generator of steam will in time cost more to produce than it is worth, coal has so many disadvantages that no one will regret to see the time when it will be supplanted hy another agent. When this is to he, is the question of the future.

Scotch Iron Product.—The ysar's production of pig iron, as shown hy the annual returns just issued upon the authority of the Glasgow Association of Iron Merchants and Brokers, has heen 932,000 tons, or 30,000 more than last year. There have also heen increases in the quantities consumed. In foundries and in the making of finished iron and steel it amounts to 8,000 tons, or a total of 302,000 toos as against 294,000 tons last year. In shipments, etc., the increase has been 130,000, the total heing 564,000 ae against 434,000 tons. And the stocks now held are an increase of 66,000, the weight at present in stock heing 745,000 as against 679,000. On only two former occasions have ths stocks been larger, and they were at the close of 1863 and 1864. The increase of 66,000 in etocks, though it is much larger than the trade had anticipated, would be not excessive considering the total make, and did not have much effect upon the market when the figures became known.

Corn Cobs for Fuel.—Mr. Ira A. Holly, Superintendent of the water works at Burlington, Iowa, reports that for the first 20 days of last December he ran his hoilers exclusively upon corn cobs. During that time the engines pumped 5,818,698 gallons of water 246 feet high; 81,466 pounds of corn cohs wero used during the time, or 4,073 pounds per 24 hours. The pnmps averaged about 290,934 gallons in the same length of time. In a letter from Mr. Holly, in which these particulars are given, he saye the duty "is ahout 14,700,000. Now figure that duty at the price we pay for eoft Iowa coal. It would take 3¾ pounds of coh to do the work of one ponnd of coal; duty figuring according to price, 55,600,000 pounds of water raised one foot high per 100 pounds of coal." This is a rather remarkable statement.

Scientific Progress.

Prof. Tyndall's Latest Word.

If asked whether science has solved, or is likely in our day to solvs, ths prohlem of the univsrse, I mnst shaks my head in douht. Behind and abeve and around us the real mystery of ths universe lies unsolved, and, as far as we are concerned, is incapable of solution. The prohlem of ths connection of hody and soul is as insoluhle in its modern form as it was in the prescientific ages.

There ought to bs a clear distinction made hstween science in the state of hypothesis and science iu the stats of fact.

Aud inasmuch as it is still in its hypothetical stage, the ban of exclusion ought to fall upon the theory of evolution.

After speaking of the theory of cvolntion applied to tho primitive condition of matter, as helonging to the dim twilight of conjecture, the certainty of experimental inquiry is here shut out.

Those who hold the doctrine of evolution are hy no means ignorant of the uncertainty of their data, and they only yield to it a provisional assent.

In reply to yonr question, they will frankly admit their inahility to point to any satisfactory experimsntal proof that life can he developed, save from demonstrahle antecedent life.

I share Virchow's opinion that the theory of evolution in its complste form involves the assumption that, at some period or other of the earth's history, there occurred what would he now called epontaneous generation. I agree with him that the proofe of it are still wanting. I hold with Virchow that the failures have been lamentable, that the doctrine ie utterly discredited.

Science and the Bible.

The *Christian Advocate* says, in reference to the first of ths ahove paragraphs ("That there ought to hs a clear distinction hetween science in the state of hypothesie and science in the state of fact"), that "no douht there is that distinction, and no douht, either, that forgetfulnese of this truth is the reason why so many prsmature assaulte have heen made on the teachings of revelation, in the name of science. 'Science, *in the state of fact,*' is no more antagonistic to the truths of ths Bible thau ons ray of the eolar epectrum ie inconsisteut with the other."

The Theory of Evolution.

The *Advocate* further says: "Prof. Max Muller makes the following strong point against Mr. Darwin's 'Theory of Evolution.' He insists that philology points out the real specific difference hstween man and the lower animals. It erects a harrier which has never heen passed. He says: 'I cannot follow Mr. Darwin, because I hold that this question is not to he decided in an anatomical theater only. There is, to my mind, one difficulty which Mr. Darwin has not sufficiently appreciated, and which I certainly do not feel ahle to remove. There is, hetween the whole animal kingdom on the one side, and man, even in his lowest state, on the other, a harrier which no animal has ever crossed, and that barrier is language. By no effort of the understanding, by no stretch of imagination, can I explain to myself how language could have grown out of anything which animals possess, even if we granted them millions of years for that purpose.'"

Deep-Sea Soundings.

Great difficulty is met with in taking deep-sea soundings hy ordinary methods when there are strong undercurrents, owing to the fact that the line is carried away hy the currents to such an extent that the length of line paid out affords no measure of the actual depth. Sr. Henrique de Lima has recently devised an apparatus to remedy this defect, a description of which was recently read hy that scieutist before the Lishon Academy of Sciences. The apparatus appears to have some valuable features. It is hased on the effects of atmospheric pressure, and consists of a cone of sheet copper, having for its hase a diaphragm of the same metal, which screws into the bottom of the cone eo that it may he readily removed when necessary. In this movahle hase there are six small holee, which allow the ingress of the sea to the interior of the cone; and to the center of its upper surface there is soldered a small vertical wire of pure silver, which occupies the axis of the cone.

To prepare the apparatus foruse the silver wire ie moistened with nitric acid, which results in the production of a thin film of nitrate of silver. The hase hsing screwed on, the cone if eusended by meane of a ring at its apex, and sunk by means of two separate weights or etones suspended by corde or chaine depending from three rings attached to the perimeter of the cone. To insure a vertical position to the apparatus, and to prevent it from heing easily turned from its course, a small float is attached just ahove the snspension ring at the apex of the cone. As the apparatus sinks into the sea the water penetrates into it through the orifices in the diaphragm and gradually rises in proportion as the pressure increases during the descent. The salt water acts on the thin coating of nitrate of silver on the wire, and turns it perfectly white hy the production of chloride of silver as far as immersion has taken place. By thie means it is determined to what hight the water has risen in the cons, and consequsntly what the pressurs has hesn; and from thess data ths depth to which ths instrument has descended is easily detsrmined hy simple formulæ. Ths auther sngests that hy suspsnding the lowsr weight hy means of an apparatus which would dstach it ou striking hottom, the apparatus would ascsnd to the surface of itself, thus dispensing with the nse of a line.

Anothsr dsvics has recsntly heeu hrought hefors the Geographical Sscisty of Berlin, which is net enly dssignsd for indicating the depth of watsr, hut also its currsnt-direction and temperature at any particular depth. This instrnmsnt consists of a hrass box hermstically closed, aud having attachsd to it an apparatus rssemhling a vans or ruddsr. Within this box a thermometer and a magnetic nesdle are contained, behind oach of which is placed sensitive photographio paper, and in front of each of which ie a small nitrogen vacuum tube. The box also contains a small induction coil. When the apparatne ie lowered to the required depth, the rudder causes it to take a direction psrallsl to the current there existing, and hence a definite direction with reference to ths needle within. The thermometer eoon acquiree the temperature of the water outside, and hecomes stationary. At this instant an electric current is ssnt to the box, which, hy meane of the induction ooil inside, lights up the little nitrogen tuhe, the violet light of which, photographically very intense, prints, in about three minutes, the position of the needle and the hight of the mercnry column upon the prepared paper. The current is then intermitted, the apparatus raised, the photographic traoing fixed, examined, and placed upon record.

Improved Treatment of Cotton Fiber.

The great world of industry knows hut very little of what it owes to the qniet, retired men of ecience, who spend their time, night and day, in inquiring into the hidden mysteries of nature, and in hringing them out, one hy one, to suhserve the constantly increasing wants of man. We have frequently called attention in these columns, to facts of this kind, and we now again refer to other matters of eimilar import. In our issue of ths 7th instant, reference was made to a recsnt interesting chemical discovery, wherehy most of the qualities and appearance of silk was given to ordinary flax fiher.

It is nowannounced that M. L. D. Kœcalin, of Basle, has devised a method, and that machinery has also heen invented and constructed whereby cotton fihsr mixed with a very small proportion of animal fihers—wool or silk—may have their entire hody uniformly treated hy one and the same process, so ae to enahle thsm to he dyed or printed with desirahle coloring matsrs, such as have hitherto heen applieahle to animal fihers only.

For this purposs vegetable oils, from which their glycerine has besn sliminated, arc, hy preference, employed. The cotton fihsr is stseped repeatedly in a hath of this mordant, either in the state of loose filaments, or of woven fahric, and either alone or mixed with silk. Between the several steepings, the fihers are subjected to pressure, in order to cause the mordant to penetrate intimately into the pores; and the fiher is then exposed to sufficient heat for fixing the mordant in it. After this treatment the fiher will he found to have become eo far assimilated in its nature to eilk or wool fiher, as to he susceptihle of treatment with the same coloring mattere with which these are treated. Olive oil has heen found to give the hest results in the ahove-described process. In operating with this oil, a quantity contained in a euitable vessel is treated with sulphnric acid, whereupon a dissociation of the fatty bodiee and a separation of the glycerine is effected, the latter, together with the excess of sulphuric acid, being removed hy washings hased on the different densities of the fatty hodies.

The product obtained is mixed with from three to four times its weight of water, producing a liquor which constitutes the mordant. If the cotton he in the form of a woven fahric, the steeping is effected hy means of a machine, in which the fahric, on issuing from the hath, passes hetween two pressing-cylinders, from which it again enters the bath, and then again passes hetween pressing-cylinders, and so on repeatedly, in order to insure the fiher being thoroughly impregnated with the mordant.

If the cotton he in the etate of filaments, or in hanks, a machine is employed such as is used in dyeing, in which the hanks are hung upon pegs or rollers, and cylinders, situated over the top rollers, are caussd to act upon the hanks, so as to subject them to pressure, at the same time that they impart to them the requisite movement for circulating through the hath.

Curious Acoustic Illusion.—M. Plumaudon, of the Puy de Dome observatory, has pointed out a curious acoustical illusion, which eome of those who use a pair of telephones in receiving may have observed. With a single telephone held, say, to the right ear, the transmitted voice appears to come from a distance to the right, while with a telephone held to the left ear, it seems to arise from the left of the listener. With a telephone to each ear, if one ear he less sensitive than the other, or if the telephone be held farthest from that ear, the voice shifts to the side of the other ear; and if hoth ears hear alike and hoth instruments are equally near their respective ears, the voice apparently proceeds from in front of the observer.

Mining Share Market.

During the past week the dullness previously existing has been greatly intensified, much to the disgust of operators and brokers. Sbould tbis stagnation continue to increase the dealers in stocks will have to seek other cbannels of operation. Witb many of tbem tbe profits fall far sbort of tbe necessary expense of continuing tbeir business.

Tbe agitation of restricting measures upon tbe operations of stock brokers is having its effect upon the market. All real evils should be eradicated; but enthusiasts are liable to go to extremes in the excess of zeal, and add to, instead of alleviating, the trouble.

But in spite of depression and agitation, the mines are producing in great excess of value over any previous period. Tbe bullion sbipments are rapidly increasing; there may be a falling off in some individual instances, but taken as a whole tbere is a decided advance in tbe amount of mining production. Nor is it a temporary increase; so many mines have been opened, and the dead, or preliminary work has been done upon them, tbat they are now in a condition to repay the great outlay tbat bas been made to render them productive. Tbe miners bave been sowing good seed, and are now reaping a rich barvest. The local value of the stocks is not real evidence of the value of the mines.

Bullion Shipments.*

Since our last issue, we have noticed tbe following bullion sbipments:

Paradise Valley, Feb. 3. $1,600; 7, $4,912.87; Wells, Fargo & Co., at Eureka, Feb. 1, $5,047.-88; Feb. 4, $3,415.12; Feb. 5, $2,400; Feb. 6, $1,000; Feb. 7, $1,058.71; Ricbmond, in Jan., $139,080.23; Feb. 3, $12,116.65; Feb. 3, $18,-986.06; Horn Silver, Jan 31, $9,646; Feb. 3, $5,200; Ontario, Jan. 31, $5,299.14; Feb. 3, $3,820.41; Feb. 6, $5,355.25; Feb. 7, $4,181.78; Stormont (on Jan. account), Feb. 2, $10,331.19; total in Jan., $48,088.72; Feb. 3, $7,906.85; Germania, Jan. 31, $2,890; Feb. 4, $3,730; Feb. 7, $2,420; Harrington & Melton, Jan. 30, $4,000; Con. Virginia, in Jan., $194,424,10; Feb. 2, $57,-661.81; Ophir, in Jan., $60,666.69; Feb. 2, $29,112.68; Frisco, Jan. 30, $8,240; Jan. 31, $9,646; Horn Silver, Feb. 2, $7,500; Feb. 3, $5,200; Feb. 5, $7,500; McCormick & Co., received from Jan. 31 to Feb. 6 inclusive, $64,-700; Feb. 7, $4,181.78; Ontario, Feb. 1, $5,299.-14; Feb. 2, $6,928.46; Feb. 4, $3,820.41; Feb. 5, $3,793.84; Feb. 6, $3,791.82; Christy, Jan. 31, $2,054.53; Feb. 2, $1,927.62; Feb. 6, $2,133.-15; Union Con., in Jan., $115,717.62; Feb. 2, $38,975.19; California, in Jan., $162,268.71; Oneida, in Dec., $10,434; in Jan., $5,478; Argenta, in Jan., $47,896; Endowment, in Jan., $4,525; Stonewall Jackson, in 1879, $79,343; Eureka Con., in Jan., 1,011,205 lbs.; Feb. 8, one week, 221,485 lbs.; Butte (Montana), two weeks, $43,000; Leeds, Feb. 6, $5,860.09; Salt Lake City (receipts one week), Feb. 6, $154,818; Hannington & Mellor, Feb. 6, $10,000.

*Desiring to make our list of Bullion Sbipments as complete as possible, we will be thankful to receive from mining Superintendents and Secretaries notice of all bullion shipments from their respective mines.

An amendment to the Constitution bas been adopted by the Iowa House of Representatives making women eligible as members of the Legislature.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

AMADOR.

Yellow Jacket.—*Ledger*, Feb. 7: This claim, which is situated on Dry creek, has not been worked much of late, owing to a great influx of water in the shaft. Pumping machinery has at last overcome this difficulty, and at present four or five men are engaged taking out rock, with good prospects.

Empire.—This property is sending sulphurets to the chlorination works that are paying well.

Gover.—At the south shaft a pump is being put down, the water being strong. At the north shaft the rock for milling is being hoisted. This mine has some of the finest hoisting machinery and works in the State.

Maryland.—Two tunnels are being run toward the shaft, and will tap it at a considerable depth. The shaft is making slow progress. Sawed logs are being used for timbers. Close to the mine is a mountain of quartz. If there is enough gold in the rock to pay the smallest margin of profit it will prove the maumoth mine of the State.

Item.—On a new gravel claim parties are preparing to ground sluice the hillside close to the Chicago mine. The idea is to uncover a quartz lode that runs through the hill. Other parties are going to convey water on claims. An open cut has been run nearly a quarter of a milo in length, and over 11 ft deep in the deepest part. It has been cut through the hardest kind of slate.

Mine Sold.—*Dispatch*, Feb. 7: We understand that Mr. Jas. Morgan has purchased the quartz mining claim of Mrs. Holtz, in Murphy's gulch near town, for the sum of $3,000, and will commence the development of the same.

BUTTE.

Mining Notes.—Oroville *Mercury*, Feb. 6: B. F. Smith, of the Putnam gravel mine, Wyandotte district, came into town Monday. He disposed of $170 worth of gold dust at the bank, taken out by him and bis partner in 14 days. Mineral Slide district, on Little Butte creek, four miles below Magalia, is coming to the front again after being deserted for several years. O. H. Riley has opened up an extensive gravel mine of 100 acres, the gravel vein running from 20 to 150 ft in depth. The gravel is small and prospects exceedingly well. A water supply of 500 inches has been obtained, and the property is so situated that a very great fall can be given for pressure. The dump is unsurpassed by any other mine in the county. Mr. Riley thinks he has a big thing, and experienced miners who bave examined the property are unanimous in pronouncing it the most valuable hydraulic claim in tbis region.

CALAVERAS.

Knox & Osborn.—Calaveras *Chronicle*, Feb. 7: Developments at the Knox and Osborn mine, in Buckeye gulch, better known by its ancient name, the Boston, continue flattering. Rock rich in free gold and sulphurets is constantly being mined, and as work progresses indications that the ledge is a true vein are rapidly multiplying. This mine is under the superintendency of Col. W. T. Robinson, a thoroughly practiced miner who is urging development with great energy. Extensive machinery is to be placed upon the mine early in spring.

INYO.

Confidence.—*Independent*, Jan. 31: At 80 ft in the shaft a drift is run 30 ft south on the ledge, which is from two and one-half to three ft wide. It will follow the ledge to the outcrop on the side of the mountain. Fine silver ore has been taken out, and a blind ledge of gold matter cut, which is very rich. The bill is seamed with small ledges, and contains one gold vein connecting and running nearly parallel with the others. The formation is favorable, and the work done so far certainly makes a good showing.

MARIN.

San Rafael.—San Rafael *Journal*, Feb. 5: No report is yet obtainable from the ore being milled in San Francisco. It is only a little sample mill, and probably never before undertook a 10-ton job. Samples of the rock crushed are examined occasionally, and the interested parties appear to be satisfied. The force at the San Rafael mine has been largely increased. A tunnel is being run to strike the ledge, eight ft wide and seven high, and timbered with 12x12. It is in about 70 ft. From all that we bear, we cannot doubt that free gold is found.

MONO.

Annenda.—*Free Press*, Feb. 5: The vein shows well on the surface, from where it has been followed, clearly defined, to the 200 level, where it is exposed for a distance of 80 ft, and shown to be 15 ft in width, of somewhat low grade but paying ore, relieved by spots and streaks of marvelous richness. From here descending to the 300 level we find the ledge not only getting more solidified, but richer and of greater width, being fully 20 ft, and followed some 150 ft in length. Still continuing down to the 400 or lowest level, we find a greater increase, 300 ft of drifting having been done on the ledge, at least 40 ft in width, 19 ft of which is good milling ore, and 5 ft rich enough to satisfy the expectations of the most sanguine, and justify the expenditure rendered for the sinking of the new shaft. The surface locations of the Addenda company are three in number, and consist of the Addenda, Silver Queen and Ben Butler, each 1,500 ft in length by 100 in width.

Standard Con.—The main shaft has a depth of 75 ft below the 700 level, and is in hard porphyry, with an increase of water. The east crosscut on the 500 level has passed through a ledge three ft wide, of good ore; have started a drift north on the ledge. North drift on 385 level is in from the east crosscut 650 ft: ledge four ft wide; have upraised from this drift 57 ft, showing a ledge four ft wide, of good ore. The south drift is in 325 ft, with a ledge in the face three ft wide, of good ore. During the week have commenced to upraise on the Cook ledge at a point 60 ft south of the main east crosscut. The ledge is three ft wide, of good ore. The north drift on the east ledge, 300 level, incline, is in 139 ft, with a two-ft ledge of good ore. South drift from west crosscut, 300 level, incline, is in 157 ft; ledge three ft wide, of rich ore. North drift on 550 level is in from the winze 55 ft, with ledge three and one-half ft wide, of good ore. The ledge in the stopes on the 550 level is eight ft wide, and looks well.

South Bulwer.—Sinking the main shaft, which is down 491 ft; timbered to the bottom; pump working well, and handles the water easily; work in winze No. 1, on 350 level, has been suspended, owing to a flow of water. This will be drained by the shaft when further depth is attained, and work resumed in a few days.

Bulwer Con.—The north drift on the Ralston ledge is in 39 ft from the Bulwer tunnel; ledge two and one-half ft wide. The south drift has a total length of 45 ft; ledge in face three ft wide, and good ore; total distance from bottom of winze, 41 ft; ledge two ft wide. The Ralston ledge is three ft wide, of good ore.

Summit.—The north drift on the 630 level is in from the shaft 73 ft; ledge two ft wide. In the south drift, which is in 82 ft, the ledge is three ft wide, and looks well.

Queen Bee.—North drift on the 400 level is in 51 ft; the ledge is looking well, and is six ft wide, of fair ore. It is improving as the drift advances.

Tioga.—The Syndicate drift, on the 520 level, is in 659 ft, and will soon connect with the Syndicate tunnel, which is only about 49 ft distant. The east crosscut from the Ralstou winze, on the 620 level, has cut some valuable stringers of ore, one of which is six inches in width. The shaft is down 760 ft.

Booker Con.—On the 400 level, 120 ft from the shaft, a ledge two and one-half ft was cut. The ledge prospects well. Crosscuts will be run east and west immediately. The south drift, on the 300 level, carries a vein about 20 inches wide.

McClinton.—*Chronicle*, Jan. 31: The south drift from the east crosscut, at the new shaft, has been extended to a distance of 67 ft, at which point a crosscut has been run west five ft, reaching the west wall; and a crosscut has been run east 22 ft, with the face still in the ledge. This crosscut will be continued to the east wall, striking it at a point about 77 ft southerly of the main crosscut, which will pretty well define the course and direction of the ledge, so as to govern the direction to run for the ore body on the lower levels. On the 500 level from the north drift, 200 ft from the shaft, the west crosscut is run 28 ft. On the 675 level the north drift is in 82 ft. The ledge is widening and looks well. On the same level the east crosscut is in 77 ft, with bunches of quartz in the face, having during the past week passed through a fine stratum of quartz.

Maryland Con.—The shaft is down 457 ft, and is in vein formation. The drifts in the upper levels are still in good ore. Crosscutting on 500 level will soon take place for the Maryland and Berdle Hyde ledges.

South Noonday.—The shaft is down 130 ft, securely timbered from the surface to the bottom.

Sonora Con.—Still driving the crosscut on the 100 level; total length of drift 94 ft. Cut a ledge of decomposed quartz and clay, looking more favorable than either of the five veins heretofore cut in the shaft and drift.

Original Summit.—Are now drifting north and south on the ledge at the 105 level. It carries from six to eight inches of very rich free gold ore; the formation is hard, but the indications are good.

NEVADA.

El Capitan.—*Transcript*, Feb. 7: The north and south drifts, at a depth of 150 ft, are being pushed ahead. In the former the indications are fair. Will start another level 100 ft below the present one before the cbute dipping north, and supposed to be the best in the claim, can be tapped.

Jacobs & Sargent's.—Gravel of a good quality is coming from the new shaft. The cement mill has begun crushing.

Wyoming.—Some very rich ore is coming from an 18 or 20-inch ledge.

Derbec.—The gravel continues to improve steadily, and the size and frequency of bullion shipments have increased by a large percentage. The cold weather and snow have, for a few days, interfered somewhat with operations, but as soon as they are gone, affairs will assume a still more satisfactory shape.

Yusa.—*Foothill Tidings*, Feb. 7: Up above Washington, continues to show "way up" in the way of a large ledge with gold all through it. It never looked so encouraging as now. When spring opens the stamps will be set at work.

Kings Hill.—Has 70 loads at the Orleans mill awaiting a crushing.

Centennial.—*Union*, Feb. 6: On Osborn bill tbe work is being done south of the main shaft, in which direction the best pay ore has always been found. The shaft is down 425 ft, and from this the No. 3 level is opened 400 ft south, giving good pay rock the whole distance. The first and second levels south also carry good pay ore. A new shaft is rising to the surface, from the lower level, 400 ft south of the present working shaft, and will be completed in a few months, when the hoisting machinery will be moved from its present location. With this new shaft it can work its south ground to better advantage, and he nearer to the best pay ore. It has 100 loads of ore being worked at the Orleans mill, which will give $70 per ton.

Flanet.—Rich gravel has been struck. The clean-up of 51 carloads (of 1,000 pounds each) amounted to over 3½ ounces of pure gold, worth $66, or $19.25 per ounce. The gravel was taken from the edge of the channel, as is evidenced by the gold being fine, whereas in the center of the channel, as is found in the "Swamp Angel" claim adjoining, a great deal of the gold is coarse. There is a large extent of ground that will take many years working to exbaust, the tunnel and drift upon which is now about 2,000 ft in length.

Idaho.—The ledge in the No. 10 drift east, which was quite small some months ago, is now of strong size, though of low grade. It is in over 1,000 ft south of the main shaft. The No. 11 drift is showing a strong vein of good ore. The east shaft, below the No. 11 drift, also shows a strong vein. The company have declared a regular montbly dividend, from the earnings of January, of $1 per share, amounting to $3,100.

Mining Items.—The new mill of the Rocky Bar company will start up in the early part of next week. It was expected that the stamps would commence dropping this week, but there are some finishing touches required that will make a few days delay. The hoisting machinery of the Allison Franklin mine has been purchased by the Fortuna mining company, and will be removed to their property near Nevada City. The Bullion mill, on the Colfax road, is running constantly on custom rock. It finished a crushing from the Ben Franklin mine a few days ago, and is now engaged on a run of rock from the Alaska mine. The Republic mining company, located at Kress' summit, will put up steam hoisting machinery this spring. The shaft is down 100 ft on a strong ledge, but pumping machinery must be put in to bandle the water, which is too quick for hand work. The Virginia mining company, a new incorporation, proposes to commence work in a short time. The location is to the east of the Maryland, which is the first extension east of the Idaho mine.

PLACER.

Bellevue Hill.—Auburn *Herald*: The Tremilling brothers have their shaft down 120 ft. At this depth they are running a west drift, which is in 20 ft. The rock in both shaft and drift averaged $70 per ton. The ore they are now taking out of the drift, it is believed, will yield as high as $700 per ton.

Alamatah.—J. M. Bryan has put up a new water wheel and pumping works on the old Alamatah ledge, near the Bellevue. He expects to prospect this lead, which he believes will prove remunerative.

Alabama.—A. J. Cook & Co. are putting a shaft down on an extension of the Alabama lead, not far from Penryn, and have a fine ledge with some good looking ore.

Scott.—Antone Smith and Jas. Denis are working the old Scott lead on Dutch ravine, about a mile below Newcastle, and are taking out some very good rock. They have ore on the dump which is estimated to go from $80 to $40 per ton.

Chicago.—The Chicago company, on the northern extension of the original old Stewart's Flat lead, formerly known as the Hanson mine; have an engine for hoisting purposes, and are down about 80 ft. They have a 2½-ft ledge, and very promising looking ore.

Sailor.—W. H. Puffer and the McCloud brothers are at present prospecting on an extension of the Sailor lead. They have hardly done enough yet to indicate the result.

Decker.—Messrs. Morris, Brooks and Price, who, for some time have been working the old Decker lead, on Dutch ravine, between Auburn and Newcastle, are down 80 ft, have a five-ft ledge, and are taking out rock that it is thought will go not less than $20 per ton. They contemplate the erection of a mill at an early day.

Rich Strike.—O. W. Wilson is prospecting a ledge about a mile and a half south of Newcastle. He is down 55 ft, and has a two-ft ledge. At that depth he is running a drift, and what rock is coming out looks first-rate. Rock taken from the bottom of the shaft assayed over $700 to the ton—gold and silver.

Yankee Hill.—Allen and Larue have purchased a gravel deposit known as Yankee Hill, near Pino, and are making preparations for working it by hydraulic. To get the requisite pressure they will have to lay about two miles of pipe, and have purchased the 22-inch iron pipe formerly in use at the old Auburn mine, which will soon be put in place.

Bonded.—A drift claim near Rocklin, owned by Frame & Co., which has been worked with good results, on a small scale, was bonded recently to a San Francisco company, who will prospect it.

Julian.—Located on Jenny Lind flat, a short distance below Newcastle, was sold to an incorporated compauy of New York capitalists, for $200,000. This mine has been developed into a fine property, with all the necessary machinery for hoisting, crushing, etc., out of its proceeds. The ledge averages between four and five ft in thickness, and is uniformly of a paying quality. The mine is well opened and in a good condition for future operations. The new owners propose to increase the capacity of the 20-stamp mill, with a much heavier set of stamps, new battery blocks, and six new concentrators.

PLUMAS.

Green Mountain.—Plumas *National*, Jan. 31: The developments are likely to show as great an ore body in this mine, as that of the famous Plumas Eureka on the south of the same mineral belt, with many of the same characteristics. For nearly two years work has been pushed forward to open the immense ore body of this mine, at the depths of nearly 1,000 ft below No. 1 tunnel and surface workings, where such rich ore was extracted. The two veins that were worked separately in the upper mine, came together about the line of tunnel No. 3, 600 ft below tunnel No. 1, forming an immense ledge. At this point a shaft was sunk 60 ft and crosscuts run which showed the ore body 80 ft wide, with a perceptible increase of width as depth was gained. No. 4, or lowest tunnel, on a level with the mill, is the point where the late strike was made. This work has been running for 18 months, and the ore has been struck sooner than was expected. There is no estimating the size of the ore body at this point, but it is certainly very large. All ore now taken out is sent to the mills. Owing to its great water facilities and location the maximum cost of working ore from this point will average $2 per ton; the grade of ore is from $6 to $40. This mine can be worked by tunnels for 1,000 ft below the present lowest workings.

Crescent.—This is a continuation of the great ledge running through the Green Mountain. Although the Crescent has never been worked to a greater depth than 250 ft, $1,250,000 have been taken out, and over $600,000 paid in dividends. A new shaft will be sunk 500 ft, the point of location being beyond the old works and towards the Green Mountain mine.

TUOLUMNE.

Ferguson Con.—Sonora *Democrat*, Feb. 7: The mine is fully opened and the reserves in sight are very large. They are erecting new hoisting works and are putting in two air compressors to supply ventilation; with these in operation, the prospects of continued dividends appear assured. The ore is paying from $20 to $28 per ton. The last run of 19 days yielded 210 ounces, or about $3,600. They have declared a dividend amounting to $5,000.

NEVADA.

WASHOE DISTRICT.

Ophir.—Gold Hill *News*, Feb. 11: The pumps are running to the 2500 level, and to-morrow sinking will be resumed in the incline. The main north drift on tbis level is 156 ft from the incline station. The east drift, same level, is in 47 ft. The joint Mexican crosscut west on the 2300 level has been discontinued and a joint crosscut started east. The north drift on the Hardy vein, 2100 level, has been turned into an east crosscut. An air compressor, driven by the weight of the descending incline cable and giraffe and thrown out of gear when the cable is ascending, is in place and only waits a heavier friction clutch to add 3,000 cubic ft per hour of 80 pounds pressure to the working power of the mine and to aid as a brake in controlling the descending cable and giraffe.

Belcher.—On the 3000 level the drifts south, east and north are being pushed ahead. The east drift is showing some favorable looking vein material, as is also that south. On the 2700 level the north drift from the crosscut east cuts quartz and bunches of ore.

California.—On the 2450 level the main lateral drift south is cutting hard porphyry, and has its face 95 ft south from the Ophir line. The east crosscut on the 2250 level, running from the main lateral drift north, is in 30 ft. From the main north drift, 1500 level, and 150 ft north of the main west drift, a crosscut has been started west to explore the ground east of the old stopes on this level. The north drift, 850 level, has reached a total length of 220 ft, and is cutting vein porphyry. Preparations are being made to resume stuking at the C. & C. shaft.

Union Con.—The east drift from the stopes on the 2400 level, continues to cut the same heavy vein formation, carrying streaks of good ore heretofore noticed; total distance of the face from the Union shaft, 283 ft. The drift south and east, running from a point where the ore came in east of the stopes, is in 35 ft. The drift east from the Union shaft on this level is now 125 ft from the shaft.

Sierra Nevada.—The south end of the mine is now worked, and men, materials, etc., for that section passed through the Union shaft. The winze below the 2400 level is down 35 ft, but has not yet reached the ore vein. The drift north on this level is still in promising vein material. On the 2300 level the main north drift continues to cut good vein matter.

Mexican.—The north lateral drift on the 2300 level is in progress toward the joint Union winze from the 2000 level.

Utah.—The incline has a depth of 200 ft on the slope below the 1750 level. The south drift, 1750 level, has reached 120 ft. East crosscut, same level, is penetrating a fine vein material, the face 100 ft east from the station.

Julia Con.—The south drift, 2000 level, headed for the perpendicular of the winze from the 1800 level, is making four ft per day. In the winze some time has been spent casing the timbers; total depth of the winze, 250 ft.

Savage.—The incline has attained a depth of 204 ft on the slope below the 2200 level. The drift from the C. N. S. shaft on the 2400 level is in 360 ft in length and making excellent progress toward the incline.

Bullion.—When the north drift on the 2250 level is sufficiently away from the station, a crosscut will be sent west into the ledge. Sinking below the 2350 level bas been resumed. Both workings are in vein porphyry with stringers of quartz.

Hale & Norcross.—The winze on the Cbollar line is down 135 ft. The flow of hot water into the winze continues strong and hinders work. The north crosscut, 2200 level, is in 135 ft.

Crown Point.—Pushing the crosscut joint with Belcher east on the 2700 level. Sinking the incline below tbe 2700 level.

Best & Belcher.—Tbe joint Con. Virginia east crosscut, 1900 level, is now in 63 ft from cutting vein porpbyry.

Sutro Tunnel.—Excellent progress is being made in the headers of both north and south lateral drifts.

CINNABAR DISTRICT.

Humboldt Bullion Bed.—*Silver State*, Feb. 5: A contract has been let to sink a shaft 100 ft on Bullion Bed. The ledge, which crops out for 2,000 or 3,000 ft on the mountain side, is one of the largest ever found in Humboldt, so far as the croppings denote. It was located in early days, but never prospected to any extent, although it is accessible at all seasons of the year, and situated on a thickly timbered mountain. The croppings assayed from $15 to $45 to the ton in silver, but this was considered too low to pay for working in early days.

EUREKA DISTRICT.

Richmond.—*Sentinel*, Feb. 6: The usual telegram from the mines at Eureka states that the week's run was $60,-000, from 900 tons of ore. During the week the refinery produced dore bars to the value of $40,000. The Manager's report contains several important items. The 400 drift from No. 15 chamber is now in 54 ft, all the drift being in good ore. The chambers are all looking very well; in the new chamber (No. 15) they have already opened out and exposed a large body of ore. A winze is being sunk from the bottom of this chamber, and a raise is being put up from the No. 13 chamber, both of which are in ore, and they expect to make a connection in two or three days. When this is completed they will have ore connection from 30 ft above the 400 to the 600 levels, a distance on the incline of the ore of 350 ft. All the other chambers are opening out very well. The furnaces are in good

Continued on Page 108.

California State Dental Association.

President's Annual Address.

The following extracts from the excellent annual address delivered before the ahove Society hy its President, Dr. S. W. Dennis, M. D., are full of interest to all who wish to see the medical profession, and all its special hranches raised to a higher standard; to all who desire the practitioners of the healing art to he men of culture and of science; not mere empirics, practicing according to remembered formulæ, or trusting to mere mechanical skill to pull through a difficult operation; hut men who have etudied life and the diseases of life; who can investigate causes, and who are ahle to make allowance for the physiological peculiarities of those whom they practice upon.

After a few words upon the President's duties, and an expression of opinion adverse to arhitrarily fixing a regular scale of fees, Dr. Dennis goes on to state that, out of 240 dental practitionere in California, only 60 helong to the Dental Association, yet that thie is a larger proportion than obtains in some other States; Michigan for example; he then proceeds as follows:

Difference in Opinion.

"Why shall we not differ in opinion?" We certainly may, hut while we claim the privilege, let us not forget that every difference in opinion is not a difference in principle. The popular idea is hest illustrated hy the case of a lady who came into my office only a few daye ago and asked my opinion. I gave it, when she said: "If I could find two dentists of the same opinion, I could decide what to do." Now, I am unahle to see why there should not he a difference of opinion among us as well as among other professions, or callings; a pathological condition in two persons might, to a superficial ohserver, appear the same, hut to the careful one quite different. I know of no way to illustrate this point hetter than to cite the frightful maladies that result from inahility to recognize conditions that demand radical treatment. A perеon may lose half or the whole of his maxillary hy an attempt to retain one dead tooth, or, more technically speaking, one devitalized tooth. It might not he agreeahle to tell the patient that he ie syphilitic or even strumous. The physicians, I mean the general practitioners of medicine, some of whom seem to think that our professional sphere is circumscribed hy mechanical principles, would say: "It is your business, only, to dig out holes in teeth and plug them." But we know hetter the houndaries of our field of usefulness.

In the theological profession also, there is a wide difference of opinion; wider, indeed, than in that of dentistry or medicine, yet the various associations of disciples all have a "saving ordinance," or one platform upon which they cau etand. Now, I helieve a study of the lawe that govern this universe, the infinite mass, the atomic and molecular relation of the elements of matter, and the application of that knowledge in our profession, is our "saving ordinance;" and, while I would not deny anyone the comfort and satisfaction of considering their future spiritual welfare, I feel like encouraging a more careful inquiry into the physical condition of our present state.

Transplanting Teeth.

A live American has gone to Paris, France, and revived the practice of replanting, and transplantiug teeth.

If there are any who do not distinguish the difference hetween replanting and transplanting, I will explain that one is returning a tooth to the place from whence it came; the other is transferring it to a new soil.

Dr. Bogue, of New York, considered this euhject quite ahly in a paper read hefore the New York Odontological Society, in which he eaye: "I hold in my hand ahout fifty references in regard to transplantation and replantation of teeth. These references range all the way from 1777 to 1877, and they are all records of experiences. These experiences are as various in their character as the persons whorecount them; hut they all tend to ehow that there is no physiological reason why replantation when necessary, and transplantation under favorahle conditions, should not prove successful," etc., etc. *Vide* Transactions for 1877.

If we had no other literature than this from which to draw a conclusion, I should eay it would he well for us to consider our cases thoroughly hefore we hid for puhlic approhation in experiments of this kind, where the transmission of disease is so likely to follow.

If the immortal John Hunter, who made syphilis in all of its varied contagion a special etudy, could not detect the presence and prevent the transmission of this disease, how can we, in our circumscribed sphere of action, expect anything hut evil results from this line of practice?

In Hunter's days experiments—for experimente they were to some extent—were more justifiahle and necessary than now, for there were not many, if any, dentists then, and artificial dentures were *almost* unknown, while now we have a few dentists, and artificial dentures are plenty, *cheap* in all cases, aud *quite* artistic in *some*.

It may not he uninteresting, however, to give authority that these operations *may* prove succeesful, ae well as that disease is liahle to he tranemitted.

[Dr. Dennie, then, details several casee on record, in which syphilitic diseaees were transmitted hy the transplantation of teeth, and showe that the method is not a new one, as most people suppose from newspaper notices of it, hut as old, at least, as the time of John Huuter, from whom, in fact, some of the cases he gives are quoted.—Eds.

Legislative Enactment.

I think the practice of dentistry ought to he legalized in this State, as it is in many other States. I look npon this as the most important step in advance. If every State in the Union, or the General Government, if you please, should limit the practice of medicine and its collateral branches—dentistry heing one—to those only who have degrees, or certificates from regularly authorized colleges for the development and perpetuity of that branch of knowledge, the standard of professional education would advance ten-fold, and thus the physical well-heing of the American people, who intrust their lives and health to the profession, would he enhanced in the same ratio. The legal fraternity may say: "Yes, one has said the State can do it, hut the General Government cannot." I said, "It could if it would." "Yes, hut it is not likely that it would, for it would have to amend the Constitution." The National Constitution has heen amended three times in 20 years, and in that time the United States has expended $3,000,000,000 in war, and crimsoned her soil with hlood hy a sacrifice of 500,000 valuahle lives, and her crippled patriots are legion. And still we are told the General Government can do nothiug for the protection of the people!

A sign, "hearing for its motto the miserahle delusion," "Dr." or "Dentist," means *nothing*. In other words, it means simply that some one is practicing medicine or dentistry, as the case may he. But when you see the title of "M. D.," or "D. D. S.," used legally, it ie evidence that the party has taken some steps towards qualifying himself; has contrihuted something toward education and in favor of educational inetitutions. Of course it has heen and will he said, "going to a dental or medical college does not make a good dentist." Will not the opponent of these views, in favor of education, he candid, forget himself for the moment, and say, as inferior as the young graduate may he, to the mau who through long yeare of close application and hard study has made his mark, that he is not hetter for having taken his collegiate courее? We know that in this city there are some men who have not taken these preparatory steps, and are hetter operators, and perhaps hetter dentists, than *some* of those who have.

But are we not prepared to say that the close observer of mechanical principles, of causes and effects, may not he much improved hy a reasonahle scholarship, under didactic teaching, upon the fundamental principles of medicine and its collateral branches?

If we do not take this ground, why should we claim our art to be a profession?

I should have to declare it to he a misnomer. In my opinion it would he a proetitution of a long cherished and noble English word.

Only yesterday, a friend of mine, from Rhode Island, said that a short time ago he knew of two young men who hargained with a dentist in his native town, to teach them all he could in one week. The dentist did so, and at the end of that time the young men went West and entered practice. It is uot necessary to go away from home for such instances; we have plenty of them under own observation. And still we find men in the Legislatnre and in the profession who oppose legislative prohihition, when they are aware of the existence of such a state of loose practice. If I desired to he popular, I would advocate the opposite, if I advocated any side at all. But I receive more satisfaction in heing with a minority on the right side of thie suhject, than I should with the unthinking majority on the wrong side. I have also the satisfaction of saying that my present position on this suhject is consisteut with my past. The records will show that the first report made hefore this association ou dental education was hy myself; and in which I embodied the same sentimeut as herein expressed.

One of the greatest difficulties in the way of the passage of a law for the regulation of the practice of dentistry, is the fear of the enactment of laws operating againet those now in practice.

Such laws are *ex post facto* in their nature and are declared unconstitutional hy the highest authority. I have no doubt every memher of our association would oppose such a law, and for own part, I am most earnestly opposed to any euch retrospective measure.

But when a Bill, or Act, ie introducted into the Legislature that shall effect only those who will not avail themselves of the opportunities of a higher professional education, or who seek an asylum among us from the effect of similar laws in other States, I shall favor its enactment; and I am unahle to see why a law of such prospective heneficial results should not have the support of the profession, the press, and the people, whom it is designed to heneflt.

Education.

Whatever difference of opinion there may he among us upon minor questions, we ought not to differ much upon this. No one feels the value of an education so much as the students of nature, who have a view of the promised land and cannot reach it. And none value it so little as those who have had the opportunity of an early education thrust upon them, and have not had the energy and indnetry to apply it to the solution of the prohlems of life. Too few obtain knowledge for the sake and love of it, more particularly when it yields no immediate results; and many are too much interested in making a good showing of what they have. Such habits of life may he termed intellectual economy, instead of intellectual growth. Thomas Starr King says: "The preparatory school aud the college lay the basis of the power and the satisfaction with which, in after years, the work of life will he discharged. Young men do not go to college to complete their education, hut to draw the ground-plan of it, and tolay theundercoursee of a future building deep and firm. To use the worde of St. Paul, in a secular sense, they are there laying up for themselves a good foundation against the time to come. And the yeare are profitahly used just to the extent that hahits of mental industry are formed, loyalty to truth confirmed, and the principles which underlie and support knowledge and culture are laid and cemented imperishably hy the masonry of application. Nobody can become wise in the hest college on this planet, hetween 12 and 20. But a youth of capacious powers can do more in those years toward enlarging the resources and ennohling the proportious of his meutal character and influence, than in twice eight years after he ehall have taken up the task of life. It is no time to look to the lower tiers of the edifice after the rafters are up and the roof is on. It is no time to he attending to a crack in the hasement, or a leaning wall, after the huilder has moved into the house with his family. The hest he can do ie to move out of it and huy another, and spend largely to have it put in friendship with mathematics and gravitation. But a student cannot remove from his mental house, in his husy years, although he may see that the ground tier of the stone is not hased right, and the walls are not thick enough for the weight they must hear. And then the misery that comes! To feel the need of fundamental instruction, which might have once heen thoroughly acquired, while the mind must act and in responsible callings, too, as though it felt secure! To he under the necessity of heing student and worker, journeyman and artist, in the eame hour, without the satisfaction that helongs to either hranch of toil, and with the hurthen of practical, and, perhaps, very important duty upon the hands and conscience—this is a species of refined and exquisite agony which many a professional man in our day experiences, and which is the penalty eitber of an enforced adoption of the duties of a profession without ample preparation, or of wasted academic hours."

The old adage, that "necessity is the mother of invention," is applicable to our department of Medical Science.

When attention was first attracted to the prevalence and progress of disease of the dental organs, any one could and was allowed to enter the profession—so-called—and practice dentistry; hut now the opportunities are so great for something more than an empirical knowledge, should they not he required to have it? It would not only seem proper, hut eminently wise, that practitioners should attain eome degree of technical education, even though it might not he all that conld he desired?

I would have every practitioner of dentistry after this date a graduate, and then all the quackery, if any, would he confined to *them*. The standard would he elevated, or there would he a higher plane than at present. As it is now, the graduate has the advantage of the non-graduate, hecause the degree of M. D., or D. D. S., is *prima facie* evidence of qualification; and, all things being equal, the community would seek the services of the former, and not the latter.

The time will never come, however, when there will not he two extremes; when the degree of natural and acquired qualification are so equalized that people will not have to eeek other evidences of worth—those of professional integrity, culture and character.

If there is any one thing in which Americans are pre-eminent ahroad, it is their deutal skill.

As much as the royalty of foreign countries may desire to encourage home art, home culture and home industry, if not to say home superiority, they have looked on thie side of the Atlantic, and to America, for the highest degree of perfection in our specialty.

Good dentistry meane industry, intelligence and skill; *bad* dentistry means indolence, ignorance and avarice. What has heen said of "language" will apply also to every department of life.

Whatever loses the vital principle of renovation and growth, tends to decay; and if mere copyists, compilers, ahridgers and modifiers he encouraged, as they are now, language surely will not he improved. Style is liahle to he antiquated hy time, corrupted hy innovation, dehased hy ignorance, perverted hy conceit, impaired hy negligence, and vitiated hy caprice; and nothing hut the living spirit of true authorship, and the application of *just* criticism, can counteract the natural tendency of these causes.

I will quote Prof. Lionel Beale, to show the danger of accepting *authority* for *fact:*

"Sufficient distinction has not, I think, heen drawn hy many hetween science and the statements put forward in her name; hetween scientific demonstration, and the facts said to have heen demonstrated hy investigations called scientific; between the actual discovery of new truths, proved heyond all question, and mere assertions, sufficiently dogmatic, dictatorial and positive, hut resting upon authority instead of upon evidence.

"Authoritative assertion damagee the interests of science, and arrests the progress of truth; for science can never acknowledge any authority whatsver. Her truth rests simply upon evidence; and the more carefully and the more minutely the evidence is sifted, the greater is the gain to science. Unfortunately, however, in every stage of scientific progress, instances are not wanting in which mere positive assertione have heen implicitly helieved, and when these have proved to he erroneous, new assertions as positive have taken their places, to he in their turn refuted, and replaced hy others. And this must ever be, if people pereiet in accepting scientific statements upon authority alone, and refuse to study the grounds upon which the statements are said to rest."

The Metal Market.

From James Lewis & Son's mouthly report we gather the following:

Copper—There has heen a eharp advance in value of Chile har copper during the past month; the sales were large and the prices ranged from £71 to £74; bcst selected advanced to £81 10s.

The charters for Decemher were 3,600 tons fine copper.

The arrivals at Liverpool and Swansea have heeu 5,656 tons; the deliveries have heen 4,928 tons fine.

The sales of furnace material have heen 6,881 tons of ore, from 8¾% to 15%, at 13s. ¼d. to 13s. 9d. Precipitate, 1,227 tons at 13s. 3d. to 13s. 9d.; 50 tons Rio Tinto leaf, included in above, sold at 13s. 11d. Barilla, Cohiga, 50 tons at Liverpool, 14s. Regulus, Chile, to arrive at Swansea, 320 tons, 14s.

The Chile exports for 1879 were 54,878 tons fine.

Stocke of west coast produce are, tons, Liverpool, hars, 26,716; ingots, 50; Regulus, 29; Swansea, hars, 4,609; Regulus, 1,870; ores, 770; equal to 32,384 tons fine, againet 30,490 tons on Dec. 1st.

Stocke of other than Chile produce are 11,582 tons fine, against 11,709 tons Dec. 1st.

Quotations Jan, 1, 1880, are—Bars, good ordinary hrands, £65 15s. to £66 10s.; and for distant arrival, £67 5s. per ton. Ore—13s. 6d. to 13e. 9d; and Regulus, 14s. to 14s. 8d. per unit.

From other sources we gain the following (at London to Jan. 6th):

At the Swansea Ticketing this day, 2,033 tons of ore, averaging 10% produce, sold at an average price of 13s. per unit.

The sales of the day amounted to 800 tons, Chile hars. Cash metal realized £66½. For parcels with extended prompts, huyers paid £67½ to £68, according to time of delivery. Some favorite marks eold at £67, and best hrands at £67½, cash. The market closed steady at £66½ for G. O. Bs., cash; £76 has heen quoted for hest selected, and £71 for Chile hars.

Australian—£74 to £76; tough cake, £70 to £72; hest select ingot, £71 to £73; India sheets, £74½ to £75½; yellow metal sheets, 6½d. to 6¾d. per pound.

From the *Engineer and Mining Journal* of New York, Jan. 24th, we copy the annexed:

The sales amount to from 3,000,000 to 5,000,000 pounds for spot and future delivery, selling up to 25 cents at the close for spot, while 25½ cents is asked for March delivery. The market for this article is in a very excited condition, being at the mercy of the companies and the speculators.

We are further indehted to the circular of James Lewis & Son for the following quotations:

Lead has advanced to £19 5s. to £19 15s. for ordinary shipping hrands; and £18 15s. to £19 per ton for Spanish soft silver.

Antimony has risen to £64 to £66 per ton for French Star Regulus.

Tin—The closing quotations are £99 for Straits with an upward tendency.

Wickenburg.—From time to time we have mentioned the fact that W. E. Smith & Co. were preparing to work the tailings of the Vulture mill hy a new, simple and cheap process, which, if euccessful, would prove to he of great importance to miners in Arizona. We now have the gratification of knowing that the process not only does the work well, hut surpasses all that was claimed for it, and far exceeds the most sanguine expectations of the gentlemen who are handling the works and own the patent for Arizona. The men in a very ehort period, with simple, cheap machinery, have reduced quite a large quantity of tailings, realizing 60,000 pounds of concentrations, worth several hundred dollars to the ton. There is not a mine in Arizona hut what can he worked for the free gold and the tailings, after heing treated hy this process, and made to yield to the last cent all the precious metal in the ore. Thc tailings at the Senator, Peck, Big Bug and other places can all he made to pay largely hy Mr. Smith's method of treating them. We think this is quite a feather in the caps of mill and mining men who have great quantities of rebellious ore to work, and hope they will confer with Mr. Smith, and allow him to introduce hie new process at every mine in the county.—*Arizona Miner.*

The Engineer.

Channel of the Mississippi and its Tributaries.—The improvement of the channel of the Mississippi and its tributaries, by an elaborate system of levees, is now being urged upon Congress. The House committee, to whom the subject had been referred, are reported in the public prints of the past week, to have taken a very sensible course in reference to it. The committee, it is said, have concluded, after a thorough and careful consideration of the whole subject, that the best mode of ascertaining the necessities of the districts affected by the river will be by personal examination and inspection. They have, therefore, proposed to send a committee to visit the localities in question, and to obtain the opinions of experts, pilots, and others who are familiar with the physical condition of the river from its mouth as far up as St. Louis. Some difference is reported to exist in the minds of this body as to whether either the levee or the jetty system is the best method of attaining the desired end. The total cost of the proposed system of levees is estimated to be about $60,000,000. Meantime, the "Mississippi River Improvement Convention" has met at Quincy, Ill., and adopted a resolution appointing an executive committee to prepare a memorial to Congress, setting forth in detail the views of the convention on the subject of the improvement of the river channel, to collect and publish statistics bearing on this subject for the information of the people and the government, and to use all proper means to promote an early and favorable action on the subject by Congress.

Plumbago as a Lubricator.—The *Engineer* gives this example of the value of black lead as a lubricator: "A fly-wheel shaft hearing, eight inches in diameter and 10 inches long, carried a load of nearly 10 tons. The bearing was supported on a box girder, and was lined with good brass. The engine could not be run, as this bearing invariably got nearly red-hot after a few revolutions; various oils, tallow, sulphur and gunpowder were tried with most indifferent success. By using a mixture of tallow and sulphur the engine could be run half an hour at a time, and once or twice has run a whole day, the shaft making 60 revolutions per minute. It was determined to have a new crank shaft with a longer bearing, but as at the last moment the use of black lead and tallow was suggested, a package of the ordinary black lead used for stoves was worked up with some tallow, the bearing carefully wiped, and the grease box on the cap filled with the mixture. The hearing never heated again unless oil was allowed to get access to it. The success of the plumbago as a lubricator was perfect. It should be added to the foregoing that while the principle of lubricating by graphite, or plumbago, is scientifically correct, and has in thousands of instances been practically illustrated, it has been damaged seriously by the use of impure graphite. For perfect success the graphite should be absolutely clean.

Proposed River between Manchester and Liverpool.—A meeting has been held in Manchester for the purpose of considering the expediency of the proposal for the construction of a tidal navigation for seagoing steamers between Manchester and Liverpool. At this meeting Mr. Hamilton Fulton, the engineer, explained the nature of the proposal, and stated that the length of the channel between Manchester and Liverpool would be about 36 miles. The minimum width of the navigation would be 200 feet, and the minimum depth at low water spring tides would be 10 feet, or about two feet more water than exists at low water over the bar at the mouth of the Mersey. A basin would be provided at Manchester end of 81 acres with 16,000 lineal feet of well-constructed wharves, and all requisites for shipping accommodation on a large scale. The estimated cost of the undertaking is £3,500,000. Mr. George Hicks, of Manchester, presented a statement as to the probable revenue, which, if realized, would give a large return upon the proposed outlay. Owing to the inability of several members of Parliament and others to attend, the further consideration of the subject was adjourned.—*Warrington Guardian.*

Chicago's Tunnels.—Chicago is much dissatisfied with the tunnels built under the river which divides that city, with the object of relieving the blockade of vehicles in the streets. When they were built, 12 feet of water was considered enough, but vessels have increased so much in size since Chicago was made a port of entry, that ships and steamers are constantly "humping" or scraping their keels on the arches of the tunnels aforesaid. The shallowness of the river is so serious a drawback to shippers of grain, coal and lumber, that tearing up and rebuilding the Washington street tunnel is strongly urged. This is a warning to large cities, lest they build streets in such a manner that ships are compelled to sail over the heads of those who frequent the public thoroughfares.

Electricity in the Future.—Dr. Werner Siemens, of Berlin, in a lecture on "Electricity in Service of Life," dwelling on the electric transmission of force, prophesied that "the energy of the solar rays, manifested in currents of air or in falls of water, may by-and-by, through the electric current, furnish all necessary heat, and render us independent of ordinary fuel."

Useful Information.

On Rotting Wood.

We condense the following from an interesting lecture recently given by Prof. Wm. H. Brewer, of Yale College, before the New Haven Board of Health:

It is well known that all woods contain certain nitrogenous, organic compounds, known chemically under the general name of *albuminoids*, and that these substances are active in inducing and favoring rot. All chemical methods for the preservation of timber from decay look towards getting this nitrogenous portion into some less soluble condition, or into some combination less liable to chemical change. When green wood is well soaked in cold water, a considerable quantity of such albuminoid matter is dissolved out, remaining in solution in the water. This solution, even when very dilute, is extremely putrescible—more so, indeed, than any person would deem possible, until he had tried the experiment. The fact is as true of the hardest woods, as maple and locust, as it is of soft wood.

To illustrate: If a few pieces of such green wood be carefully freed from bark and all foreign dirt, and put into the purest cold water and let stand at the ordinary temperature of 60° or 70° Fahr., the water soon begins to become turbid or opalescent; this opalescence increases, in two to four days a thin pellicle forms on the surface, active putrefaction sets in, along with an abundant growth of ferments, and the liquid soon becomes peculiarly and pungently stinking. The odor naturally varies with the kind of wood used, but in all cases it is very rank, fully as much so as the same amount of *animal* matter in solution. The intensity and rapidity of putrescence vary, of course, with the temperature, the kind of wood, and the degree of concentration of the solution.

As in the case of other putrefaction, what the gases are which produce the exhalations, we are entirely ignorant. It is probable that they are organic compounds of simpler molecular constitution than the albuminoids which furnished the necessary elements.

If kept long enough, and of sufficient concentration, there is an abundant fungoid growth in the solution, and if kept in the light it grows darker in color, gradually becomes sour to the taste and smell, but continues offensive in odor for a long time; in bottles partly filled, it continues to smell bad for two years. Where the solution is kept in the dark, the odor seems more offensive than if the decay goes on in the light.

In the free air and full sunlight (the condition to which piles and various other wooden structures and vegetable matter in swamps are subjected) along with the putrescence, a white fungus growth begins on the surface of the wood, which rapidly becomes slimy. This forms much more abundantly on the ends of the grain of the wood than on either the radial or tangential sides. If the solution is poured from the wood and kept in a separate vessel, and in the light it grows dark, as already described, but the fungus growth goes on, modified, of course, by the temperature and the degree of concentration, or until the decay has become complete.

If the wood continues to be placed in successive portions of clean water, the soluble matter continues to be extracted for several months, even if the blocks be very small, and the tendency towards putrefaction grows less and less. Finally, however, the soluble matter appears to be removed, the water then remains clear, and the wood ceases to be covered with fungus growth, at least to any visible extent.

Timber, when thoroughly water-seasoned, is known to be very durable, and it is probable that it is so merely because of the removal of the soluble and putrescible albuminoids.

Experiments tried with the same woods in sea water, and in brackish water (made by mixing two measures of fresh water with one of sea water), show similar sanitary results; they are even actually intensified. The turbidity begins sooner in sea water than in fresh; the film on the surface is more abundant, and the smell is more disgusting. Heart-wood and sap-wood act essentially alike in this matter, the difference is one of degree rather than of character.

The suggestiveness of these facts is almost too obvious to need comment, and yet I will add a word. Vast quantities of wood and vegetable matter, decaying in water or in swamps, are too common.

If piles about our wharves and similar structures do not smell so badly, it is merely because the solution is more dilute. The decay goes on, however, and so with vegetable matter decaying in swamps, sawdust in ponds, and so on to the end of a long chapter. The trouble has sometimes been attributed to the obvious gases evolved, notably to light carbureted hydrogen, which one may see bubbling up, with nitrogen and carbonic acid, through the water of ponds, where sawdust, or vegetable matter, is decaying on the bottom. As I have maintained in a paper read at a previous meeting of this association, I cannot believe that either of these latter gases of decay seriously affect health. These latter experiments on woods only confirm the views then expressed.

The exhalations of swamps, or of vegetable matter decaying in still water is universally regarded as unwholesome, in climates where for a part of the year, at least, the wear the is as warm as we have it. So far as I know, there is no exception to this on the whole earth, and hence the general sanitary bearing of the observations here recorded need not be further argued.

Blacksmith's Hammer Signals.

When the blacksmith gives the anvil quick light blows it is a signal to the helper to use the sledge, or to strike quicker.

The force of the blows given by the blacksmith's hammer indicates the force of the blow it is required to give the sledge.

The blacksmith's helper is supposed to strike the work in the middle of the width of the anvil, and when this requires to be varied the blacksmith indicates where the sledge blows are to fall by touching the required spot with his hand-hammer.

If the sledge is required to have a lateral motion while descending, the blacksmith indicates the same to the helper by delivering hand-hammer blows in which the hand-hammer moves in the direction required for the sledge to move.

If the blacksmith delivers a heavy blow upon the work and an intermediate light blow upon the anvil, it denotes that heavy sledge blows are required.

If there are two or more helpers the blacksmith strikes a blow between each helper's sledge hammer blow, the object being to merely denote where the sledge blows are to fall.

When the blacksmith desires the sledge blows to cease, he lets the hand-hammer head fall upon the anvil and continues its rebound upon the same until it ceases.

Thus the movements of the hand-hammer constitute signals to the helper, and what appear desultory blows to the common observer, constitute the method of communication between the blacksmith and his helper.

To Saponify Petroleum Oils.—According to the London *Journal of Applied Science*, the following is the practical mode of operation in the particular case of a refined petroleum: Stearic acid is the fatty matter employed, and, upon being melted, is poured into the petroleum—in the proportion of about 15 parts of fatty acid to 100 of petroleum. After thorough intermixture has been effected by stirring, the mixture may be saponified in the usual way. It is recommended, however, that animal or vegetable fatty matter be added to it before saponification, the result being an improved product, the proportions recommended being two of acidified petroleum to three of fat. Either soda or potash may be used in saponifying, and the soap produced will be hard or soft according to the alkali employed and the proportions taken. The product is represented to be actively detergent, and to be free from tendency to putrefy. We give the foregoing for what it is worth. From the neutral chemical character of the mineral oils, it would appear that the result of the operation just described would be simply a case of mechanical suspension, and not one of chemical union, as in the case of the soaps proper. The process is affirmed to be applicable not only to the native mineral oils, but likewise to such as may be obtained from schist, asphaltum and other sources. The novelty of the process seems to consist in first saturating the mineral oils with a fatty acid, and then saponifying in the usual manner, the capacity for saponification having been imparted by the addition in question.

Good Health.

The Feet in Winter.

Sometimes in washing the feet in warm water a great deal of scurf or whitish soft substance may be scraped from the soles. This is dead skin, dried perspiration, and other accumulations, all resulting from a want of personal cleanliness. These accumulations occur most in winter, when washing the feet is neither as convenient nor agreeable as in summer time. Many persons suffer from cold feet, simply from a neglect to keep them clean. Few suffer thus in summer time, one reason for which is that the skin is moist, the pores are open, a free evaporation takes place, and the blood is invited to the surface. In winter the skin is dry, harsh and cold. To keep them constantly warm and comfortable is indispensable to good health, and to do this the surface must be brought to the condition of summer—that is, must be soft and somewhat moist, instead of being harsh and dry. This may be soon brought about by soaking the feet in warm water for half an hour at a time daily, using most freely a very stiff brush, with good soap. After the skin has become soft and smooth, a good washing with soap and warm water twice a week during cold weather will greatly contribute to a healthful condition of the feet as well as to personal comfort. If the feet are kept unexceptionably clean, and are nevertheless inclined to be dry, considerable benefit will be derived by rubbing into the soles every morning a little sweet oil, 20 or 30 drops to each sole, with the palm of the hand, patiently and well, the object being to secure by artificial means, that softness and moistness which is known to favor evaporation and invite thither the flow of blood. If in addition, the feet were placed in cold water regularly every morning (when not unwell) not over two inches deep, and remaining in not over half a minute in cold weather, then rubbed briskly dry with a coarse cloth, next with the hands, all followed by a brisk walk or stamping for a minute or two, or until they begin to feel comfortably warm after the cold bath, an improvement in the condition of the feet would be secured in a reasonably short time, which would largely compensate for the trouble taken.—*Hall's Journal of Health.*

A daily action of the bowels, says *Hall's Journal of Health*, is essential to good health under all circumstances; the want of it engenders the most painful and fatal diseases. Nature prompts this action with great regularity, most generally after breakfast. Hurry or excitement will dispel that prompting, and the result is, nature is baffled. Her regular routine is interfered with, and harm is done. This is a thing which most persons do not hesitate to postpone, and in the case of riding to town, a delay of one or two hours is involved. This never can occur with impunity, in any single instance, to any person living. This very little thing—postponing nature's daily bowel actions—failing to have them with regularity—is the cause of all cases of piles and anal fistulas, to say nothing of various other forms of disease: fever, dyspepsia, headache, and the whole family of neuralgias. A man had better lose a dinner, better sacrifice the earnings of a day, than repress the call of nature; for it will inevitably lead to constipation, the attendant and aggravator of almost every disease. To arrange this thing safely, breakfast should be had at such an early time as will allow of a full half hour's leisure between the close of the meal and the time of leaving for the cars.

Soda for Burns.—All kinds of burns, including scalds and sunburns, are almost immediately relieved by the application of a solution of soda to the burnt surface. It must be remembered that dry soda will not do unless it is surrounded by a cloth moist enough to dissolve it. This method of sprinkling it on and covering it with a wet cloth is often the very best. But it is sufficient to wash the wound repeatedly with a strong solution. It would be well to keep a bottle of it always on hand, made so strong that more or less settles on the bottom. This is what is called a saturated solution; and really such a solution as this is formed when the dry soda is sprinkled on and covered with a moistened cloth. It is thought by some that the pain of a burn is caused by the hardening of the albumen of the flesh which presses on the nerves, and that the soda dissolves the albumen and thus relieves the pressure; others think the burn generates an acrid acid which the soda neutralizes.

What Smoking does for Boys.—A certain doctor, struck with the large number of boys under 15 years of age he observed smoking, was led to inquire into the effect the habit had upon the general health. He took for his purpose 38 aged from 9 to 15, and carefully examined them. In 27 he discovered injurious traces of the habit. In 22 there were various disorders of the circulation and digestion, palpitation of the heart, and a more or less taste for strong drink. In 12 there were frequent bleedings of the nose, 10 had disturbed sleep, and 12 had slight ulceration of the mucous membrane of the mouth, which disappeared on ceasing the use of tobacco for some days. The doctor treated them all for weakness, but with little effect until the smoking was discontinued, when health and strength were soon restored. Now, this is no "old wife's tale," as these facts are given under the authority of the *British Medical Monthly.*

Pitting in Small-Pox.—Somebody has ascertained the curious facts, in small-pox, that poor people are pitted least, rich people are pitted most, and no classes are pitted under their dress. Poor people have less light in their homes; the rich have plenty of light, and under this dress there is of course less light than in either case. The explanation according to this observer, is a scientific one. The sunlight consists of three primary colors. The red, the blue and the yellow rays have distinct and characteristic properties: the yellow gives light, the red gives heat, and the blue gives actinism. Now, the pus of variolar pustules absorbs, by its yellow medium, this actinic rays, which results in corrosion of the tender flesh at the base, thus leaving pits.

Importance of Sleep.—A medical man, discoursing upon sleep, makes this remark: "One man may do with a little less sleep than another; but, as a general rule, if you want a clerk, a lieutenant, a lawyer, a physician, a legislator, a judge, a president or a pastor, do not trust your interests to any man who does not take, on the average, eight good, solid hours of sleep out of every twenty-four. Whatever may be his reasons for it, if he does not give himself that, he will snap some time just when you want him to be strong."

Temperature of Baths.—A cold bath should not vary much from 75° Fahr.—under, rather than over. A temperate bath is from 75° to 85°; tepid, 85° to 95°; warm, 95° to 100° and over. The temperature of the body, in health, is about 98°. For cleansing purposes a hot bath is most desirable, but should be indulged in only occasionally, and for a very few minutes at a time. A hot bath excites and increases the circulation, a warm bath soothes and tranquilizes, and decreases the pulse.

SAN FRANCISCO:
Saturday Morning, Feb. 14, 1880.

TABLE OF CONTENTS.

GENERAL EDITORIALS.—Electric Light; Double Reel Compound Geared Hoist; Advantages of Incorporatione to Mining; The U. S. Fish Commission on the Pacific Coast; Catalogue of the Pacific Coast Fungi, 97. The Week; Fraudulent Representations in Mining; The Dodge Crusher and Pulverizer; Railroad Items; Mining in Maine, 104 Legislative Matters; Aztec Ruins; The $20,000 Prize for Harvesters, 105. Present Ventilation of the Cometock; The Hofmann Patent, 108.

ILLUSTRATIONS.—Double Reel Compound Geared Hoist, 97. Ground Plans of Aztec Ruine in New Mexico, 105.

CORRESPONDENCE.—Wiegand's Amalgam Refining; The Alkalinity of Tulare Lake Water, 98.

MECHANICAL PROGRESS.—Iron in Bridge Building; Why Does Steel Harden? Improvements in Boiler Making; Do Not Burn Your Tires in Welding; After Coal, What? Scotch Iron Product; Corn Cobs for Fuel, 99.

SCIENTIFIC PROGRESS.—Prof. Tyndall's Latest Word; Deep-Sea Soundings; Improved Treatment of Cotton Fiber; Curious Acoustic Illusion, 99.

MINING STOCK MARKET.—Sales of the San Francisco, California and Pacific Stock Boards, Noticee of Assessmente, Meetings and Dividende, 100.

MINING SUMMARY from the various counties of California, Nevada, Arizona, Idaho, Montana and Utah, 101-108.

NEWS IN BRIEF on page 109 and other pages.

THE ENGINEER.—Channel of the Mississippi and its Tributaries; Plumbago as a Lubricator; Proposed River Between Manchester and Liverpool; Chicago's Tunnels, 103.

USEFUL INFORMATION.—On Rotting Wood; Blacksmith's Hammer Signals; To Saponify Petroleum Oils, 103.

GOOD HEALTH.—The Feet in Winter; Soda for Burns; What Smoking Does for Boys; Pitting in Small-Pox; Importance of Sleep; Temperature of Bathe, 103.

Business Announcements.

Boarding School for Boys, East Oakland, Cal.
Postpouement Notice—Atlanta Mining Co.
Assessment Notice—California and Oregon Land Co.
Delinquent Sale—Gover Mining and Milling Co.

The Week.

The cold wave has surged back upon this coast, and still holds ite position, which, with its chilling influence on business movements, has a retarding effect. There is so little being done in the labor channel that workingmen are complaining of privation, arising from the lack of wages, to purchase the necessaries of life. They have had a procession, and have appointed committees to call upon the leading corporations and ask for the discharge of Chinese employees.

There is great dullness in stock transactions, hut conciderable activity prevaile in legitimate mining properties. Capital is seeking investment in well-proven mines; and speculators are securing claims which promise rich returne in the future.

The distress in Ireland is awakening the generous sympathies of our men of wealth, who are evincing their humane eensatione by liheral contributions to the relief fund. Mr. Mackey hae donated $10,000, and the Nevada hank has given $25,000 to this henevolent cause. We hope to see the list of similar gifts largely increased. Our Irish citizens have decided to omit the usual celebration of St. Patrick's day, and instead, to devote the time to an entertainment, the proceede from which are to be applied to the relief of their countrymen at home.

The free fight shooting, which is becoming too prevalent just now, has resulted in the death of a woman in Oakland, who was unfortunately passing near the ecene of trouble and was instantly killed by a random bullet.

The Legislatnre is actively at work, but more time seems to he given to getting up and introducing bills than to deliherate discussion of their merits. Hasty legislation ie to be deplored, and the public would be more satisfied with the work, were due and proper consideration given to the measures propesed.

THE nomination of John M. Morton as Internal Revenue Collector for the San Francisco distriot has been rejected by the Senate by a vote of 42 to 10.

THE Treasnry Department a few days since purchased 375,000 onnces of silver for the Philadelphia, San Francisco and New Orleans Mints.

Fraudulent Representations in Mining.

When any great channel of entsrprise is successfully inaugurated, all legitimats industries accessory to it are dsstined to flow in its course. Thsy are ths sustsining streamlets that supply the current of the channel. It is where they rightfully helong. It is where they should he found. The channel would he inoperative if they were not present. Thsy constitute the arterial hlood, which, flowing through it, imparts life and energy to it. In strict accordance with the lawe of adaptation, they, while there, are in their true sphere.

Bnt fungi will always he found npon the richest soil, and parasitee will ever thrive npon the moet nutritious vegetation. So in all channels of intrinsic value, there will he found schemers and fraudulent designers, who, going with the current, will hold forth illusive projecte to ensnare the unwary, and hy deception and falsehood inveigle their victims into disastrous speculations. If the loss entailed upon the unwary was the only evil arising from their pernicious operations, it, perhaps, would not be much of a matter of regret. It might in the end he a benefit hy inculcating the growth of caution and due investigation. But, unfortunately, such ie the fruit which matures from deceitful transactions. The deception which has led them into losses, to them appears but a natural result of the operations which legitimately helong to the channel upon which they have emharked with their venture. They do not discriminate between the false and the true; overlooking their own credulity and incautiousness they condemn all that is worthy of approhation. They are like the navigator who, lured hy false lights, should anathematize all lighthouses; or like the merchant, who, smarting under an ill-advised speculation, should declaim againet all commercial transactions.

In no field of enterprise are the above remarks more appropriate than in that of mining. Properly conducted mining is not only a legitimate industry hut it is also a profitahle one. Its inducements for the investment of capital are greater in the way of profit than that of any other industry. Unfortunately, many who desire to avail themselves of its henefits are incapahle of deciding hetween true and false statements in mining narrations. Knowing the desire of the many to engage in prosperous undertakings, the schemer ever stands ready to mislead them hy false and glowing statements of the value of mines that are really worthlsss. Their only aim is to possess themselves of the money of those who listen to their lying assertions. There is not a mining district in the world but hears irrefutahle evidence of the false representatione of this clase of men. The result has heen that others who would operate in mines and hring intelligence and capital to aid in their development, are restrained from doing so hy the wails of the losere. As far advanced as miniug is at the present day, it would be still further on the way of euccessful operation, were it not for the result of the frands that have heen perpetrated by these schemers, who have placed lights where they would allure their victims to ruin.

It is the duty of the press to take a bold and firm etand against these artful and dishonest manipulators. Wherever a fraud ie institnted it should he promptly exposed. If the papere in the locality of these mining claims that are so falsely overrated would at once decry the intended wrong they would ultimately reap the benefit of such a course. A few such errors, if allowed to culminate, would at last ruin the reputation and retard the progress of really good mining camps. They would keep capital away and would dishearten and discourage men of enterprise and ability from investing there. If they were checked in their incipiency and put down by just exposure, the evil they would have produced would he averted. A condition of prosperity and success would exist, where, else, ruin and failure would ensue. In the dissemination of the truth, the local journal would have strengthened ite own fonndation; while in ahstaining from telling it, or in aiding in the fraud, it would certainly he weakening and undermining it. For a temporary gain it would establish a permanent evil. The journals in mining camps, particularly, should he like the beacons on the coast, warnings of the dangers to which the venturesome are liable.

NEW MILL IN BODIE.—The new Standard-Bulwer 30-stamp mill started up on Sunday last to test the machinery, and was found to work well in every particular. It was formally opened and etarted crushing ore on the 10th, and, everything proving satisfactory, the structure was turned over to and accepted by the officers of both companies. The mill is the finest in the district.

THE Pacific Mail Co. have announced passenger rates from New York to San Francisco. The rates for passage have been fixed at $75 for first-class, and $35 for steerage. In opposition, the Railroad companies offer the following rates: First-class, $100; second-class, $75; third-class, $45.

IT is reported that 75,000 ehares of Father De Smet etock, Black Hills, have been sold to a company of English capitalists for $1,500,000.

The Dodge Crusher and Pulverizer.

We saw in operation this week at the Union Iron Works, a comhined rock hreaksr and pulverizer, which is the invsntion of Mr. Miles B. Dodge, the machine heing intended to equal in capacity a 10-stamp mill, with any specified size of screen. The arrangement is very simple, and it seems to perform its duty in a satisfactory manner.

The rock hreaker is a No. 2 mountsd on a platform at ths upper end of the casing which encloses the pulverizing harrel, a spout directing the ore crushed hy the rock breaker into the harrel, thus acting ae an ore feeder as well. The rock hreaker is geared direct to the ehaft of the harrel, both running in unison hy means of one helt, hut adapted to he disconnected at pleasure.

The harrel is one of that class of pulverizers in which the ore or cement is pulverized hy meane of halls or rocks. The chamher ie made polygonal instead of cylindrical, the angulated eides overlapping each other, the eides either heing formed of hars of iron with spaces hetween, or of plates. The harrel we examined has six overlapping sides, an opening heing left at each lap.

The crushed ore comes in from the feeder at one end, and the harrel or chamher is rotated, a numher of cast-iron halls being put in it, which grind the ore. While the ore is heing ground up, the material drops off the overlapping edges of the angulated sides past the openings, the ore and halls dropping at each lap.

By having the revolving harrel made with angulated sides, a more perfect and rapid pulverizing action is ohtained. When the chamber ie made like a cylinder, the material simply slides around and is not sufficiently agitated. With the angular sides, however, the material is tumhled over and over irregularly. As one of the sides risee, all that material upon it is snddenly thrown down, and is soon covered and powdered hy the material on the next side, the halle dropping at each lap upon the ore. This dropping action is readily heard when the machine is running. In cylindrical crushers the balle slide in mass, and the ore slides or drags along the inside of the cylinder, wearing out hy friction the hare or grates. In this the halls drop with the ore, and act after the manner of stamps, pulverizing the ore by impact rather than hy attrition. This facilitates the action of pulverizing, and doee not cause so much wear. Mr. Dodge assures us that the ore ie crushed evenly, and no "slimes" (or very little) are produced, which usually cause so much trouhle in amalgamation.

The screens used on the machine to which we refer, are of No. 40 mesh, hut Mr. Dodge considers No. 20 fine enough for gold ores of this State, a statement which he says he will prove to those who hring him samples to work.

This combined crusher and pulverizer is made in snch a manner that the whole can he put up in a few hours after arriving at its destination, and is in fact a complete ore-reducing appliance.

At the Globe Iron Works, Mr. Dodge has one of hie comhined rock breaker and rolls—the same pattern as those of which he has sold so many in Colorado. Thie is simply a rock hreaker, mounted on the same frame with a pair of Cornish rolls, the ore hroken by the breaker being directed to the rolls, where it ie crushed to the size of wheat. The rolls are arranged on elastic bearings, so that a spike or hammer even will pass through withoutinjuring the rolls. The hreaker has jaws of wrought iron instead of hard steel, Mr. Dodge finding this iron preferable. This machine is cheaper than others, and warranted not to hreak. There are a great many of them at work in Colorado, where they are highly appreciated. One has lately heen sent to Virginia City, one to Columhus, Nev., and one to the Mariposa Land and Mining Co.'s mines.

When only one machine is to be used, Mr. Dodge recommends the comhined breaker and pulverizer. When two pulverizing barrels are to he used, he prefers to sell with them, a rock hreaker and rolls, the ore from these passing into the pulverizing harrels.

These machines are set up in running order at the places indicated, and are worthy of examination and criticism by all interested in ore-crushing machinery.

THE MERCURIAL SEPARATION OF SILVER FROM GOLD AND OTHER AMALGAMATED METALS.—In our issue of January 31st we drew attention to the Wiegand Amalgam Refining Process, now owned by the Nevada Amalgam Refining Co., of which the inventor, Conrad Wiegand, at Virginia City, Nevada, ie Superintendent and Manager. It was our purpose at that time to have printed a communication from Mr. Wiegand in relation thereto, and the article was in type. Pressure on our columns, however, forhade. But in to-day'e issue the communication appears. We need only remind our readers that its peculiarity in freedom of etyle is due to the fact that it was written more ae a private letter to us than for print. But instead of culling the facts communicated and ourselves preparing an article, we believe it would he more gratifying to our readers for us to print his offhand letter juet as received and explain its style. We commend his communication, which we have taken the liherty of giving sub-headings to, to the attention of all amalgam producers. It appears under the caption of "Wiegand's Amalgam Refining," on page 92.

Railroad Items.

On the 10th inst. the Nevada Central railroad from Battls Mountain, on ths C. P. R. R., was completed to the city of Austin. This line establishes a new era in the mining industry of Reess river and the adjacent country. This extensive and rich mining country has hitherto lahored under very great disadvantages on account of the difficulties of transportation and travel, and the consequsnt expense of mining operation. But hy the completion of this road it is made one of the most accsssihle and valuahle mining sections on the Pacific slope. Its resources are practically inexhaustihle, comprising mines of gold, silver, copper, antimony, galena, iron and other metals which offer an inviting field to capitalists who desire to engage in mining as a legitmate business. This district of valuahle mining and grazing country occupies the central portion of the State, and will hereafter contrihute largely to its production of the precious metals and its material prosperity. The people of Lander county are juhilant over the completion of the road. This enterprise has heen carried to a successful termination hy a syndicate of New York capitalists, who have shown indomitahle energy in completing the work against apparently insurmountahle ohstacles, caused hy the severest winter known eince the occupation of the country hy the whites. It has reached Austin in contract time, and secures the $200,000 suhsidy voted hy the citizens of Lander county.

The track of the Southern Pacific R. R. is now 23 miles east of Casa Grande, and ahout 40 west of Tucson. From the 2d to the 10th of February, there were 81,900 feet of steel rails laid. The company hope to have the road completed to Tucson ahout the 4th of March. There are at present en route from Pennsylvania eteel raile enough to complete the road to ahout 60 miles east of Tucson hy the 1st of May.

A suhscription hlock of Sonora Railroad stock, projected to run from Guaymas, on the Gulf of California, to the southern extension of the Atchison, Topeka and Santa Fe Railroad syetem in New Mexico and Arizona, was recently sold in Boston for a bonus of $5,000. The last sale was at $350, and it may he interesting to some to know that the same block was sold each time. The first 30 miles of road are to he constructed immediately, heginning at Guaymas.

The removal is announced of the main offioe and clerical offices of the Kansas division of the Union Pacific railroad to Omaha. Only the General Superintendent's and Assistant-General Passenger Agent's offices remain in Kansas City.

The Senate Committee on Corporatione has adopted Beerstecher'e Railroad Commission hill as a suhstitute for all others. It is amended in several respects. As recommended for passage, it fixee the salary of each Commissioner at $4,000; of the Secretary at $2,000; of the Bailiff at $1,200; traveling expenses other than transportation to he paid hy the State. Railroads and traneportation oompanies are allowed to carry the Commissioners and their employees. The Board ie empowered to employ counsel other than the Attorney-General and Distriot Attorney. In case of exigency, all suits to which the Board ie a party shall have precedence over all other business except criminal husiness. Section 11 is amended so as to provide that the fixed ratee of charges shall go into effect on the twentieth day after the same shall have heen posted and a printed copy has been served upon any agent or officer of any copartnership company or corporation at each of the stations, depots or landing places affected. A section was added to provide for the transfer of the property of the Transportation Commissioner to the new Board; also another section providing that the salaries and expenses shall be paid out of the general fund of the State Treasury.

Mining in Maine.

The mines in Maine have been quietly developed by Eastern capitalists for some few yeare past, and under their judicioue management mining has grown into such great proportions in that State that it now holds a prominent rank among the producers of silver and copper. It is evident from the progress made in this direction that henceforth mining will he classed among the leading interests there; and it is not unlikely that the success which has attended this industry, will soon give birth to a spirit of speculation, which has ever been associated with mining operations.

There are nearly 100 mining companies in active operation. The majority of them are in silver oree, the halance in copper.

Private compaies comprise about one-third of the number. The mines are supplied with machinery of the most approved character, and although the shafts have not reached a depth of 800 to 1,000 feet, it is capahle of prosecuting the work at that depth.

Old Californians who have returned to their homes in that section are investing and working in the mines, and their opinion is that the mineral deposits are of immense value.

We gather the above general viewe from the *Maine Mining Journal*, a new paper, which tho interest of the mines has called into existence. It is ahly conducted, is cautious in its expressions, and is a beautiful specimen of typographical art.

Legislative Matters.

Senator Conger has introducced the following bill affecting mining corporations:

SECTION 1. It shall be unlawful for any officer of any mining corporation incorporated or existing under the laws of thie State, to be pecuniarly interested, directly or indirectly, in any contract for the milling of oree, the furnishing of supplies or in the performance nf any work nr any business nf the corporation. Any violation of this sectiou shall be punished by imprisonmont in the State prison for not less than ous nor more than ten years, nr hy a fine of uot less than $1,000 nor more than $20,000, or by hoth such fine and imprisonment.

Another hill introduced hy the eame Senator rogulates the issuance of certificates nf stnck of cnrporations as follows:

All certificates of stock of any corporation incorporated nr existing under the laws of this State, shall he isened to and in tho name of the real owner thereof; or, if isened in the name of a trustee, the certificate muet also give the name of the person for whom the same is held in trust. All certificatee of stock issued in diegard of this section shall be void.

Aseembly bill No. 75, introducod by Gorley, limiting and regulating the sale of mining stocke, has been adopted without discussion hy a vote of 69 to 10. We gave this hill in full in our last ieeue. It prohibits "waeh sales;" makes hrokere give customers written accounts of transsctions and date thereof; prohibits hypnthecating or loaning of stocks, etc. Violation of the provisions nf the act is accounted a misdemeanor, punishahlo hy a fine of not less than $1,000 nor morc than $10,000, and imprisonment in Stete prison for from eix to twelvo months. One nf the speakers, when voting, eaid this hill should be stigmatized as "An act to prohibit men from using their credit."

When the hill came up in tho Assembly, the Committee on Mines and Mining had offered eeveral amendmcute, which were voted down with singular unanimity by the Houee, the committce itself not voting for them. The first amendment was to Sec. 1, to make the purchase or sale of shares in stock boards a misdemeanor instead of a felony.

Gorley said that the hill had caused eome disoussion throughout the State, and wae a just measure. If the hill had heen suhmitted to the Board of Brokers it could not have heen amended in eny way hetter calculated to eatisfy them, then hy the committee. They showed the hand of an expert. There are men who would gladly sink the hill rather than allow one ducat to slip through the fingers of the hoard. Most of them have not seen the misery which he had witnessed. If the business wae conducted honestly, there would he no necessity for the hill.

Felton desired to strike out the provision against hypotheceting etocks. He said thet he weut to the committee aud aseured them that the hill would reduce the mining businese to a mere cash hasis. No other business in the Union was similarly conducted. It would drive away hundrede nf millions of capital. It was a legitimate enterprise, and if properly restricted, should he fostered. To prohibit the hrokere from hypothecating the etocks would put a etop to the business. There are hille here which will properly regulate the business, he thought.

The Committee on Finance and Waye and Meane, reepectively of the Seuate and Assembly, met on Wednesday, Senators Conger, Carlock and Baker, and Assemhlymen Brooke, Cuthhert and Coffman heing ahsent. The Pardee hill was suhstituted for the hill prepared hy the committee, and was considered hy sections, commencing with Sec. 3,628 of the Political Code, which was adopted hy the following vote, which may he considered as a test vote: Ayes—Johneon, Traylor, Ryan, Pardee, May, Downes—7. Noes—Moreland, Brown of Yuhe, Del Valle, Leach, Morse, Hartson—6.

Hertson said that the minority would not interfere with the perfection of the Pardee bill.

It ie understood that the minority, which repreeents a majority of the Aseemhly Committee, will report the committee bill.

Ryan said that if stock was taxed at thie time corporations would resist, and no property of theirs would be taxed.

Pardee suggested the essessment of stock ahove par, as it would he the same thing, there being little ahove par.

After several other amendments, Johnson moved that the Pardee hill as amended he reported favorahly to both Houses, which wae carricd hy the following vote: Ayes—Senators Johnson, Traylor, Sears, Pardee, Brown of El Dorado, and Ryan, and Assesmhlymen May and Downes. Noes—Senator Moreland, Asemhlymen Leach, Morse, Hartson, Brown of Yuha, and Del Vallo. The reports will be made nn Saturday.

In the Senate, Hittell'e bill, relating to removing officers in mining corporations, wae recommitted to the Judiciary Committee, to incoporate the same in the codes.

After a long debate, Senate hill amending section 358 of the Civil Code hy allowing private individuals to litigate the validity of corporations was read a eecond time, and orderod to engrossment.

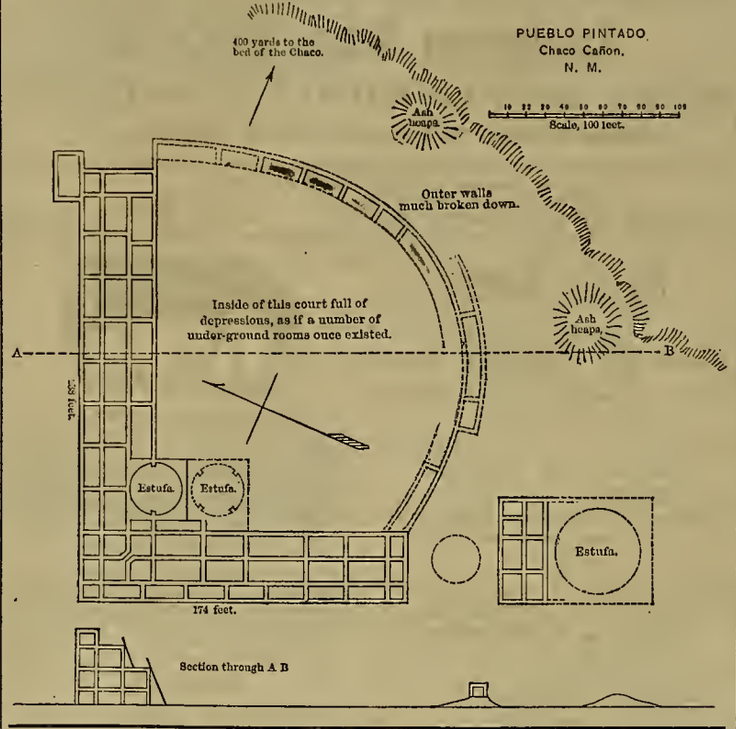
After a long dehate, Chase's hill amending eections 294 and 295 of the Civil Code requiring 10% of the capital etock of corporations to he paid in hefore filing articles of incorporation was indefinitely postponed.

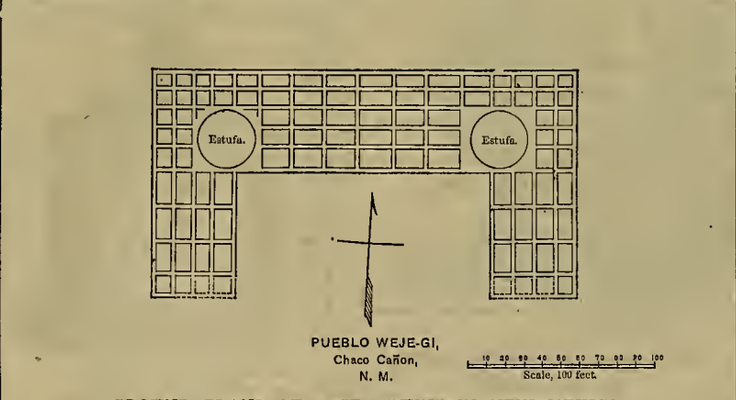
Johnson has introduced a bill enforcing the section of the Constitutinn making direotnrs of corpnrations liahle, and dcclaree nny attempt to ovade its provieion a felony. It has heen reforred to the Jndicisry Committee.

Wsson's hill, amending an act for the protection of minere, provides that where mines are sunk heyond 300 feet in depth, an extra shaft ehall be sunk to connect with the main shaft, es a mode of escapo from nndergrnund accidents; and that all machinery, cahlee, reols, cagee, etc., ehall be kept in perfect ordor and inepected every three mouthe hy a competent person. Failure to comply with the foregoing makes tho company or owners of mines respousihle for all accideuts caused thereby.

Aztec Ruins in New Mexico.

The fame of the Aztec empire has been sounded by poet, novelist and historian ever sinco the vestigcs of their ancient civilizetion first came to the eyes of moderu explorers. Of late years ecicnco has applied its severer methods of analysis to the ruine of their pre-





GROUND PLANS OF AZTEC RUINS IN NEW MEXICO.

hietoric greatness, and though much has heen learned concerning Aztec hahitatione and the minor materials which entered into their life methode, there is much still to he discovered. The latest investigation relating to these matters was made hy the Government Survey of New Mexico, in 1877, results of which have heen lately puhlished. We shall preeent to our readers a few engravings showing the ground plans of the most notahle ruins which were discovered in the Chaco canyon in New Mexico. These ruins are pre-eminently the finest examples of the numerous and extensive remains of the works of unknown huilders to be found north of the seat of the ancient Aztec empire in Mexico, and of which there is comparatively hut little known even in this day.

The Puehlo Pintado, shown in the engraving on this page, is the first run of any extent met in an approach from the southeast. Referring to the ground, which is the result of careful measuremente carried mainly over the floor of the eecond story, it will he seen that the principal portion consists of an L-ehaped huilding, the two wings of which, facing south and east within 20 degrees, measure upon their exterior eurfacce 238 and 174 feet. The extremitiee of these wings are conneoted hy a wall or row of small houses springing in an aroh from one to the nther. Msny of tbe small apartments in this row have their walls so well preserved thet they can he readily messured.

Almoet the entire area of the oourt thus inclosed, approximately 200 feet hy 160 feet, presents a very irregulsr and broken surface, as though it had hecn nearly all occupied hy underground apartments, the roofe of which falling in produced the great deprcesions and mounde which now exist. The two outer walle, which are now standing in placce ahout 30 feet in hight, indiceto an original elevation of at least 40 feet, unbroken by any apertures excepting the emallest kind of windowe. The northeru walle present the largest unbroken surfaco. The northwest corner aud the western wall are much moro broken down. The two interior longitudinal lines of wall in hoth wings ere intact throughout most of their lougth to the top of the eecond and third stories, while the well fecing the court barely extende up into the second story.

Twelve miles from the Puehlo Pintado, and on the north side of tho canyon, are the next important ruins, although therc are several small onee on the way. The Puehln Weje-gi, as Simpson calls it, is situated close under the hluff, and is a rectanguler structure built around three sides of an open court which faces almost due eouth. Its exterior dimensions are 224 hy 120 feet. The walls are still etanding to a considerahle hight, aud indicate at leest three stories. They are huilt in much the same style as those of the Puehlo Pintado, of small tuhular pieces of sandstone arranged with a heautiful effect of regularity and finish. This ruin is remarkable for the perfect symmetry of the arrangement of the rooms and of the *estufas*, a close ecrutiny and careful measurement failing to detect eny deviation. The rooms are small, the largest being 8 by 14 feet, and the smallest 8 feet square. The *estufas* are each 30 feet in diameter, and are placed just within the two elbows of the huilding.

AT 11:30 A. M. on Monday the last spike necessary to complete the hranch of the Atchison, Topeka and Santa Fe railroad to Santa Fe was driven hy Gov. Wallace, Gen. Hatch and eteff, the Legielature and other notahles attending. There is much rejoicing at Senta Fe.

JAMES W. CLAYTON, for fourteen years olerk in the Houee of Representatives, died at Baltimore recently.

The $20,000 Prize for Harvesters.

The lest meil from Austrelia hrought ns files of Adelaide exchanges which contsin reports nf the conteet for the prize of $20,000 offered hy the govornment of South Australia for a comhined reaping and threshing machiue. It is somewhat dieheartening to announce at the outeot that tho contest was only a partial success, eo far as hringing to view a full-fledged and well-working combined machine is concerned. The magnificent prize has failed to secure the objects aimed at in its offering.

There had heen 27 entries for the government prize of $20,000, hut at the roll call only 14 responded and brought forward their machines. Of these there was one from the United States, entered hy S. L. Gaines, of Oregon; the others were of colonial invention. Mr. Gaines was ohliged to retire from the field soon after starting up. His excuse wae that he had lost a pulley from his machine on the voyage, and the smaller one with which he attempted to work would not serve the purpose. The colonial machines did better, and after making their rounde, the grain was poured upon a tarpaulin and examined hy experts. One machine was found to crack the wheet, hut otherwise to yield it clean and in marketahle condition; hut those following the mechine found so much wheat on the ground thet its "saving" qualities were rated low. Another machine, which the reporters decrihe as having the appearance of an "infantine dredger," yielded wheat not eo badly cracked as the preceding, hut it was not eo olean. The third machine to finieh its round produced "very clean grain, with little waste." Tho fourth machine, which is pronounced hy the *Observer* to "stand a chance of distancing ite competitors," was entered hy Mr. Phillipson. It reaped, threshed and hagged the grain, and in "all reepects did its work hetter than any other exhihited."

We shall select, from the list of machines exhihited, one on sccount of its American origin, and othere hecause they succeeded in turning out threshed wheat on the trial field. Mr. Gaines' machine was an adaptation of the Californian header, with a threshing and winnowing attachment. From the header the grain ie thrown hack upon a "draper," or rather three "drapers." Theee are revolving endless hands of canvas; one at eech side carries the heade, which are cut off to a central draper, which in its turn conveys them hack to a thresher, which efterwarde forwarde the chaff and wheat into a winnowing arrangement, where they are separated, the chaff, straw and other ruhhish heing scattered over the field.

The machine which is spoken of ahove as wasting grain was planned in this way: On the "off" side of the arrangement is a Ridley reaper contrivance for stripping the grain and cheff off the straw, from whence it is thrown up into a chute, which conveye it to a winnowing machine, carried upon the "near" eide, one pair of wheels and a very long and etrong axle supporting hoth winnower and reaper. The driver occupies a place with respect to the reeper portion of the machine similar to what he would were the winnower absent; but on the platform, to the left of him, stands a man with a scoop, who continually gathers up the cleaned wheat from a receptacle in the platform heneath hie feet, and deposite it in a hag hung up in front nf him. This labor appeered to he very heavy, and the continual hohhing up and down seemed unsuited for very hot weather. The wheet and chaff is passed through a number of sieves until it is separated into fine wheat and refuse, and at the end of the round the wheat begged by the second men is laid upon the ground, whilst the chaff, chogs and other waste is cleared out of the hody of the winnower.

The machine which did the best work at the trial was made hy Mr. Phillipson, of Victoria. The local report eaye: The grain passes intn the mechine the same as in the ordinary etripper. After paesing through the heatere it falls on to an apron which elevates it to the top of the machine, and whilst it is being carried up it is acted upon by the wind from the front fan, which blows a portion of the chaff out of chimney at top of machine. The grain and straw then fall on to a strew-csrrier which carries away all the rough straw and discherges it at the hack. The grain then falls through a hopper on to the riddles, end while falling is acted on hy the wind from the second fen, leaving nothing hut white heads and drake to he taken out of the wheat, which is effected by the riddlee, the white heads passing out on the off side into a set of elevetore which convey them hack to the heaters to he rothreshed. The clean wheat paeses out on the nesr eide into a set of elevators, and is then elevated and discharged into hags which stand on a platform on near side of machine. The drake falle from the riddles into a hox pleced to receive it. The hags when full are sewn up and tipped on to the ground. The machine requires two men tn work it.

Of the machines which were hronght upon the ground, hut for some reason or other did not start, there were various styles, and they are described as "like a dredger," "a threshing machine mounted on the hack of an ordinary reaper," "like a smutter in a flour mill," "like an emigrant wegon," etc. There was to he another trial in the weck following the one we have mentioned, and the next Australian mail will douhtlese bring the results of it, and it ie to he hoped that something more definite may he attained than wae hrought out at the first trial.

Heat in the Silver Mines.

Those who have never personally inspected the lower levels of our mines may obtain some idea of the degree of heat to be found therein by visiting the Savage works at the change of shifts. The men—packed together as close as they can stand on the cage—are popped up out of the shaft all steaming hot, for all the world like a hunch of asparagus just lifted from the pot. They make their appearance in a cloud of steam that pours up continuously from the "depths profound," and are dimly seen until they step forth upon the floor of the works. As the men land and separate, each carries with him for half a minute his little private cloud of vapor. As this passes off the man is seen to be naked from the waist up, his skin as wet as though he had just been lifted out of a pool of water. The men bring up with them—besides the steam—an amount of heat that may be felt by the spectator as they pass.

All this is at the top of the shaft, where it is considered quite cool—what, then, must it be hundreds of feet below, where the men started from—down where the water stands at 157° Fahr.? Down there no steam is seen—it is too hot for it. It is only when the hot, moist air coming up from the lower regions strikes the cool air towards the top of the shaft that it takes the form of steam. Down where the men come from you must keep your hands off the pump column and the pipes, and if you pick up any iron tool you will at once put it down without being told to do so. Down there they handle things with gloves on, or wrap rags about the drills they are guiding and iron apparatus they are moving; and down there, too, you will learn to keep your mouth shut after you have drawn a few mouthfuls of hot air into your lungs. Perspire? It is no name for it. You are like a sponge that is being squeezed. You are ready to believe that you have 10,000,000 pores to every square inch of surface, or as many more as any authority may mention, and that all these pores are as big as the cells of a honey-comb. You go for ice water, and it almost seems to hiss as it passes down your throat—you keep going for it, and thus, in a short time, find out what becomes of the tons and tons of ice that are daily consumed in the mines. Remain below among the miners for an hour or two, and when you are finally popped out at the top of the shaft, all red hot and steaming, among the other asparagus sprouts, you will appreciate the beauty, the light, and the coolness of the upper world.—*Virginia Enterprise.*

THE number of men available for military duty in the United States is stated by the Secretary of War to be 6,516,758.

Scientific and Practical Books on Mining, Metallurgy, Etc.

Published or issued, wholesale and retail, by DEWEY & CO., MINING AND SCIENTIFIC PRESS Office, S. F.

BY GUIDO KUSTEL,
MINING ENGINEER AND METALLURGIST.

Roasting of Gold and Silver Ores, and the Extraction of their respective Metals without Quicksilver. 1870.

This rare book on the treatment of gold and silver ores without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and explains the why and wherefore.

It contains 142 pages, embracing illustrations of furnaces, implements and working apparatus.

It is a work of great merit, by an author whose reputation is unsurpassed in his specialty.

Price, $2.50 coin, postage free.

Concentration of Ores (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequaled by any other published, embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Millman, Metallurgist, and other professional workers in ores and minerals; which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery etc., which alone are of the greatest value. PRICE, $7.50

Copp's Hand-Book of Mining Laws.

Henry N. Copp's hand-book of mining laws, just issued, contains the United States mining laws and instructions thereunder, a digest of decisions, forms, list of mining patents issued, etc. The digest of decisions alone is a very valuable thing, giving, as it does, in brief form, all the decisions of the Secretary of the Interior and Commissioner of the General Land Office in relation to mining matters. These are all under proper headings for easy reference. Forms are given for notice of location, proof of labor, notice of forfeiture, miners' lien, application for survey, patent, etc., affidavit of improvements, etc. There is also a list of patents issued for mining claim from July 26th, 1866, to August 1st, 1877. The book is of pocket size and very convenient for all who are interested in mines. It will be sent post-paid for $1, on application to Dewey & Co., 202 Sansome street, San Francisco

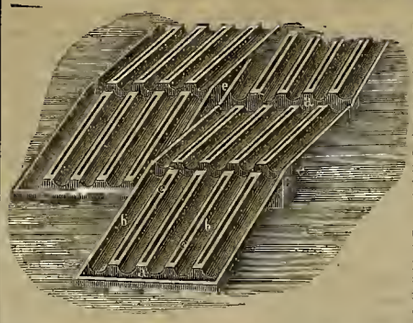
The Explorers' and Assayers' Companion.

(THIRD EDITION.)—NOW READY.

468 octavo pages, bound in library or pocket size. Price, $6 From all booksellers or direct from the author,

J. S. PHILLIPS, M. E., Etc., 702 California street, S. F.

Howland's Under-current, Mill and Sluice Riffle.



This invention meets a want which has long been felt by Gravel Miners and Millmen, viz.: that of a simple, cheap Riffle which will save the largest possible amount of gold or sulphurets, with the least possible waste of quicksilver. That this Riffle answers all these conditions will be apparent to any practical man who takes the trouble to examine it. The arrangement of this Riffle is such that there is a strong, unobstructed upper-current to carry off and break up the gravel or cement, and a slow under-current, checked by numerous riffles, which give gold or sulphurets a better opportunity of settling than if they were exposed to the force of the main current.

In this Riffle there are cast troughs for the quicksilver, which extend entirely across the sluice, and while they are so placed that the current will naturally pitch towards them, and give every opportunity for amalgamation, the quicksilver is fully protected from flouring or leakage. There is no mechanical skill required in taking out or replacing the sections.

Full particulars in regard to this invention can be obtained by applying to

STEIGER & KERR, of the Occidental Foundry, 137 First St., S. F.,

Who have the sole right of manufacturing this Riffle, and who will receive and attend to all orders.

Kendall's Spavin Cure
Is a sure cure for spavin, splint, curb, callous, spraius, swellings, galls, lameness and all enlargements of the joints or limbs. It will completely remove a bone spavin without blistering or causing a sore. It is also as good for man as for beast, and is used full strength at all times of the year with perfect safety. A cure which we are knowing to is a person who suffered 15 years with hip-joint lameness and was permanently cured two years ago with Kendall's Spavin Cure. Remember we claim it will cure a bone spavin and completely remove the bunch without blistering.

Office U. S. Marshal, Western Dist. of Michigan, } Kalamazoo, April 15th, 1879. }

B. J. Kendall, Enosburgh Falls, Vt.—DEAR SIR:—I received the two bottles of your spavin cure forwarded by express in January last. I am happy to state that it performed all your advertisement called for. In three weeks after I commenced using it the spavin was entirely removed and a valuable horse restored to usefulness. Very truly yours, JOHN PARKER.

Send for illustrated circular giving positive proof. Price, $1. All Druggists have it or can get it for you.

THE FAR-FAMED
AMERICAN LUBRICATOR.
Patented November 14th, 1876.

The American feeds oil into the steam pipe of the Engine, at a point above the throttle valve, THUS INFUSING THE STEAM WITH FOAM OF OIL, and as the Lubricated Steam passes through the Throttle, Governor, Steam Chest and Cylinder, it Lubricates all those parts.

EVERY DROP OF OIL IS VISIBLE as it passes into the steam pipe.

It imparts a regular motion to Engines, because it Lubricates the Governor Valve.

It will pay for itself in fuel every two months, in Oil every seven to 10 months, in wear, packing and labor every four months

It does all the above with absolute constancy, and with the small amount of Oil as shown in Catalogue, which please send for.

For Sale by

Ingersoll Rock Drills.

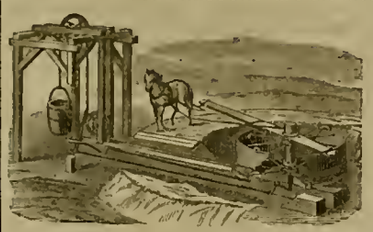
In use in the largest and best Mines of the Coast.

HAS AUTOMATIC FEED.

Has less Repairs.

Is Lighter and more Easily Adjusted than any other Drill.

Our DRY AIR COMPRESSORS are the most Economical Compressors in the Market.



MINERS' HORSE-POWER.

This Power is especially adapted to working mines, hoisting coal or building material, etc. It will do the work of a Steam Engine with one-tenth the expense. One Horse can easily hoist over 1,000 pounds at a depth of 500 feet.
The Power is mainly built of wrought iron, and cannot be affected by exposure. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending bucket. The frame of the Power is bolted to bed-timbers, thus avoiding all frame work. When required these Powers are made in sections for packing

A Card from Architects.

The California Architect and Building Review.

Office, No. 240 Montgomery Street, San Francisco, Cal.

It is with pleasure that we publish the following from prominent Architects in this city:
Believing that a journal of its kind is a necessity on this coast, and judging from what has appeared in the "Quarterly Architectural Review," we are led to believe that the CALIFORNIA ARCHITECT AND BUILDING REVIEW will be worthy of generous support and encouragement. We therefore pledge our cordial sympathies, personally, and hope that the enterprise will receive kindly recognition and liberal support from all Architects and Builders and the public generally. (Signed) David Farquharson, Wright & Sanders, S. H. Williams, Thos. J. Welsh, P. Hueme, John Marquis, B. McDougal & Son, Wm. Mooser, Wm. Curlett, Mecker & Banks, W. C. Hoagland, S. & J. Newsom, B. Henrickson.

Mines and Works of Almaden.

Translated from "Annales des Mines"
BY S. B. CHRISTY.

Full geological description of this famous Quicksilver Mine, illustrated by maps and plans of the works. Complete description of the Quicksilver Furnaces and Condensers, etc. 48 pages octavo—paper cover—price (post-paid) 50 Cts. Published and sold by DEWEY & CO., 202 Sansome Street, S. F.

[CONTINUED FROM PAGE 101.]

working ordsr. They have now running No. 1 and No. 2 on ore, and No. 4 ou refinery by-products and purchased ore.

DUNDERBERO.—The contractors have stopped the 500-ft west crosscut; total distance from the station, 123 ft. Five hundred-ft south drift ground continues very hard. During the week the ore vein had almost entirely disappeared, but looks much better to-day. The ore vein is about 18 inches wide, and looks very promising. The new crosscut above the upraise from the 400 level, referred to in my last, has advanced 30 ft, and expect to cut the ore from the upraise in about 10 ft more. The drift above the 400 level still continues in low-grade ore and vein matter.

BELLWHACKER.—Have shipped ore as per returns, and have about 15 tons still at the mine, which will be sent down in a few days, together with whatever more we get out by the end of the month. The stopes from which we are taking this ore look much the same.

RUBY.—The lode in the crosscut, in the intermediate level between the 400 and 500 levels, is reported to he two ft wide of good ore.

EUREKA CON.—First level—East drift in 159 ft. Third level—West drift in 61 ft. Seventh level—Northeast drift in 94 ft; south drift in 145 ft; north drift in 80 ft. Eighth level—South drift in 44 ft. Tenth level—East drift in 117 ft. Eleventh level—East drift in 71 ft.

K K.—Wednesday last shipped 150 tons of high-grade ore to the Richmond works for reduction.

SILVER CONNOR.—Mr. John S. Capron showed us yesterday one of the finest specimens that we have ever seen taken from this district. It showed a large amount of free gold and silver. The company has 20,000 tons of ore in sight that has not been touched.

BRISTOL DISTRICT.

OHIO.—Pioche *Record*, Jan. 31: Has made a valuable strike. Tho work has heretofore been on a spur to the west of the main ledge, believing that they were on the right track. About a week ago they were led to work to the east of the old works, when the main ledge was struck and a large body of ore was uncovered. This company will erect a water-jacket furnace and a mill, as they have both smelting and milling ore.

ARIZONA.

COPPER MT. DISTRICT.—From a private letter from Clifton, Jan. 20: It may be of interest to you to know something of the mining interests and prospects of this portion of the country. We are in the Copper Mountain mining district, which was opened up by the Lezinskys in working the celebrated Longfellow copper mine—north of the Gila river, between the Frisco and Eagle rivers. The district has heretofore been worked for copper, but is now being more thoroughly prospected, and proves not only to be very rich in copper, but in gold and silver also. The copper belt seems to lie in the center, on what is known as Chase's gulch, where the Longfellow mine is located, and is very rich in copper. North of that is the Gold camp, where very rich gold quartz, placer and hydraulic mines are worked. South of the copper belt, where I am, on Gold gulch, placer mines have been worked for years by Mexicans with considerable success. Now we find extensive quartz leads carrying gold, silver and copper; but we think the silver will predominate, as all assays show more or less of that metal, although I have taken out gold rock that went over $10,000 to the ton, some samples of which I sent to my brother in Los Angeles. Our camp is new, and but little work has been done; but with $10,000 gold, from 40 to 250 ounces silver and 30% copper, we feel very much encouraged, as all the lodes seem to be deep and permaneut. We think all we require is time, a little capital and hard labor, to develop ono of the richest mining camps in the United States.—J. E. E.

MONTANA.

PENOBSCOT.—Helena *Independent*, Jan. 22: We learn from advices received from Capt. Ryan that this mine is opening out in the lower workings and looks especially promising in the old bonanza shaft, where the vein is 15 ft wide. For the last 30 ft the ore body has been 15 ft thick, and is said to carry two ounces of gold to the ton. Sixty ft west of this shaft a winze, now down about 55 ft below the 200 level, has passed through good ground all the way, some samples of the richest carrying as high as 40 ounces of gold to the ton.

BLACK SWAN.—This mine, situated a mile above Unionville, near Oro Fino gulch, is now attracting a great deal of attention. It was discovered by the Spragins brothers and has been developed by them into a first-class bonanza. During the last summer 208 tons of unassorted ore from the eight-ft vein of the Black Swan were crushed, which averaged $20 per ton. They are now running a tunnel which, when completed, will tap the vein 160 ft from the surface.

BELT MOUNTAINS.—O. I. Olingsr, one of the discoverers of the silver mines located in the Belt mountains, about 60 miles from Benton, has brought in some very fine specimens of ore, which assays from 100 to 600 ounces per ton. These mines were discovered in December last, and are known as the Barker mining bonanzas.

ROCKY MOUNTAIN.—This late discovery is located on the west side of McClellan creek, about two miles east of the Bonanza Chief, in Jefferson county, and is a very promising silver lead. It has a four-ft crevice, and samples of ore, recently assayed at the United States Assay Office in Helena, were found to contain 333½ ounces of silver to the ton, and also a trace of gold.

WHEATLAND.—Ths breast of the drift carries three ft of ore and gangue, consisting of iron pyrites, copper pyrites and black oxide of copper. Galena is coming in in small quantities. Assays have run as high as eight ounces of gold per ton, 67 ounces of silvor and 9% copper.

BAXTER.—There are over two ft of ore in the lower level, 130 ft below ths level of the Diamond tunnel. The crosscut on the 220 level bas just cut the north vein, and drifting will be at once commenced.

MOUNTAIN BOY.—Butte *Miner*, Jan. 24: Two hundred tons of ore, carrying 90 ounces of silver per ton, will soon be shipped to the smelter from this mine.

VOLUNTEER.—In the bottom of the main shaft tho ledge formation is about 12 ft wide, eight ft of which is free milling and four ft black ore carrying considerable manganese. A lot taken from the body of free ore, not sorted, hut shipped as it came out, milled between 40 and 50 ounces in the Silver Bow mill, and 90% of the assay value was saved. A drift has been run east from the bottom of the shaft on the ledge, the face of which shows about seven ft of free ore and two and one-half ft of black or manganese ore.

MAXIMILIAN.—The ledge on this mine is narrow but high grade. The shaft is down 55 ft following an ore body varying in width from 12 to 30 inches. From the hottom a drift has been run east on the ledge 110 ft, where the ore body is wider, being from two to four ft, but not so rich. The drift west from the bottom is in about 75 ft, and the face shows a streak of high-grade free ore.

CARLOTTA.—This mine adjoins the Maximilian on the west. The shaft is down 60 ft, following the same chute of rich ore encountered in the adjoining claim. The east drift from the bottom is in about 65 ft, the ledge in this drift running from eight inches to two and one-half ft in thickness. The intention is to make connection with the west drift from the Maximilian, the two mines at present being run in conjunction. This will greatly facilitate their working.

ITEMS.—The inclemency of the weather compelled the suspension of work on the John Haney. At the Lena they are drifting east and west from the bottom of the shaft. The ledge at present is somewhat broken. The Nettie is panning out its usual quantity of high-grade free ore. The ore body in the crosscut from the bottom of the Gray Rock shaft is looking finely. Nothing new or startling to report from the Alice. They aro taking out considerable fine-looking ore at the Moose. Water compelled the Shannon to shut down for the winter. The Buffalo is looking well; showing some rich ore and a great deal of low grade.

THE W. B. ASTOR.—Helena *Independent*, Jan. 22: This valuable mining property is situated on Democrat mountain, two miles from Georgetown. The adit level, which is 1,000 ft long, has been shot out its entire length to nearly 8x7 ft in size, and an engine chambsr 30x30 ft, and averaging 25 ft high, has been excavated at a distance of 800 ft from the north of the adit and 200 ft from the surface of the mountain, vertically. The entire average of the grades of ore—not including concentrating or dump ore, which averaged nearly $100 per ton—for eight months was within a fraction of 500 ounces per ton. The tunnel was run in on the south wall for the first 400 ft, and in that distance shows but little mineral. From that point a crosscut was run for the north wall, a distance of 50 ft, cutting a fine body of mineral, and from here on to the engine chamber and 150 ft beyond, the adit is continued on the north wall. Stope No. 1 commences at the crosscut and is carried 30 ft in hight and 125 ft in length, showing ore all the way. In some places there are eight inches of solid ore that mills 350 ounces. This stops is now being worked. No. 2 stope is 75 ft further west. This is 50 ft long and 30 ft high. Five ore was taken out here, leaving a good show of high grade. Directly under the stope, on the tunnel level, the ore streak widens to 18 inches; six inches of this running 3,300 ounces of silver per ton, and the remaining 12 inches, which carried a considerable proportion of rock, milled 500 ounces of silver per ton. Stope No. 3 is opened for about 100 ft in hight and a like distance in length. This stope has yielded large quantities of unusually rich mineral, four lots of ore, all more than ton lots, yielding 1,466, 974, 609 and 860 ounces of silver per ton. No. 4 stope, adjoining the last named on the west, has been opened a distance of 50 ft in length and 40 ft in hight. This is now being worked and shows as much as 18 inches of quartz and ore, a lot of more than a ton, milled a few days ago, y elding silver at the rate of 589 ounces per ton without classification. The deep shaft is now about 70 ft below the level of the tunnel, and 270 ft from the surface.

IDAHO.

SHAW'S MOUNTAIN.—Boise City *Statesman*, Jan. 24: Mr Walter Coffin, one of the lucky owners in the Paymaster mine, situated on Shaw's mountain, was in town yesterday. There are a large number of specimens from the mine on exhibition, which are very rich in free gold. The ledge is now thoroughly opened and bids fair to be one of the best mines on the range. This and the Sunrise mine, in the same district, will both be ready to turn out a large amount of ore during the coming season. The ore from both mines will average at least $100 per ton. Thess mines, and several others in the same district, are near the Idaho City stage road, and from 10 to 12 miles from this city.

DEEP CREEK.—Idaho City *World*, Jan. 23: Rich quartz mines have been struck on Deep creek, a country very little prospected and lying about 35 miles westerly from Salmon City.

UTAH.

WASCO.—Salt Lake *Tribune*, Jan. 23: This mins has paid from the top down, and still shows a body of good pay ore in the bottom. Work was some time ago suspended on account of bad air, want of machinery, and the low price of lead. The character of the ores in this mine is carbonate. Assays show 45% lead and 40 ounces silver.

MAGNOLIA.—A new strike has been made near the town of Shauntie, by Daniel McNamarra, called the Magnolia. It is the finest kind of smelting ore, going high in silver, and 60% lead.

CONTACT.—A new strike in the Contact is creating some excitement here. This claim is situated near the celebrated mountain Queen mine, in old Pruess district, six miles west of Frisco.

CAVE.—The Cave mine is shipping 20 tons of ore to Frisco per day. Fine bodies of high-grade ore are constantly being encountered in this mine. A working force of 20 men is employed upon it. It still increases in size and richness.

HORN SILVER.—The Horn Silver mine is running two stacks steady under the management of Frank Fohr.

MINING NOTES.—In North Star a fine body of ore has been developed in the Osceola, also in the Hidden Treasure, Burlington and Bell Flower. Considerable work is being done in and around Star district upon a number of mines. In the Foothill camp of Star district, five miles from the end of the gaded part of the Utah Southern extension, and five and a half miles from Millford are some very promising claims. The Golden Era, Ariel, Vicksburg, Minnesota, Liberty, Esmeralda, Cortege (gold), Vulcan, Day Dawn, Hope, Blue Jacket, Apex and many others, all showing ore, and work progressing on most of them. Lincoln, Bradsbaw and other adjoining districts are looking up. Rocky district is now showing up a fine body of copper ore. And the same district bas been yielding large quantities of iron ore for flux.

Present Ventilation of the Comstock.

The Comatock mines, from end to end of the lode, are now better ventilated than at any time since the depth of 1,000 feet was reached in them. The aystem of air connections is so perfect that in all the principal galleries of the lower levels is found quite a brisk breeze. We hear hut little complaint about the heat at the present time. Next the miners will be growling about the cold and will be obliged to work in overcoats and mittens. The lateral drifts of the Sutro tunnel will constitute a great underground river of pure air running through half the length of the lead at a depth of 1,600 feet. The air in this great gallery will be kept pure and brisk by the many connections with large vertical shafts, with the main Sutro tunnel and with the numerous drifts and crosscuts tapping it at various points along its course. Below this is the great north-end air gallery running from the C. and C. ahaft by way of the Ophir to the Union shaft. This ia at a depth of 2,000 feet below the surface. The mines are now so arranged that they can be worked at any depth that may be required, so far as a supply of air is concerned. It will only be necessary to keep up connections with the present system of galleries and shafts. Air may thus he carried to the center of the earth; hut as regards the bringing out of the water, that is another question. However, a way to manage it will he found. At one time in the history of the Comstock we were in just as much douht about our ability to ventilate the mines at great depth, hut we now find that we have only to make proper openings and the air will go down to the lowest points; circulate through such galleries as may he prepared for it and presently come to the surface at a point to which it is led in order that it may escape. Were two shafts sunk to the depth of 10,000 feet the air would rush down one and up the other in case of their heing connected at the bottom hy means of a drift. The greater the depth at which such connections are made the stronger the rush of air that passes through them. This is plainly to he seen at the Belcher mine, where a depth of 3,000 feet has been attained.—*Territorial Enterprise.*

The Hofmann Patent.

EDITORS PRESS:—It was hardly to he expected that Mr. Kustel would willingly acknowledge the paternity of those tailings, the assay of which tells so heavily not, in my view, against his metallurgical skill, hut against his perhaps hastily sxpressed opinion. I frsely confess that I have sometimes heen ohliged, much against my will, to leave as much in my tailings.

As I seem to hs the only person, hesides Mr. Kustel, who has treated gold-hearing sulphurets at these works, and as Stswart's copper ore tailings are easily distinguished hoth hy minsralogical and *stratigraphical* featurss from the othsrs, there is not much room for douht. But let that pass; I have no desire to press the point. The question at issue is as to the propriety of granting a patent on the so-callsd Hofmann process.

I will ask Mr. Kustel, in all sincerity, if I were to rs-treat, hy common amalgamation, ths ore which I have already worked hy the Plattner and Kiss processes, would that constituts a new process or a patentable *invention?* And if not, why not? And if so, ws havs only to take the number of known processes for the extraction of gold, silver, copper, lead, zinc, antimony, arsenic and sulphur, all of which frequently occur together, and comput, hy the ruls of permutation, the numher of different "combinations" that may he made, in order to form a faint conception of the numher of patents which we may expect to see granted shortly, in which case I should pity ths patent department.

Why did not Kustel and Hofmann patent the Plattner-Patera combination tsn years ago? It may he impertinent to ask this, yet under the circumstances it is natural.

I have no animosity against either of the gentlemen concerned in this question, and am willing to pay anyone for a really new and bensficial *invention*, hut I do ohject to having my adopted profession trammeled hy frivolous patents; and I must say that Hofmann's "combination" pressnts itself to me as one of those "ohvious suggestions of common senss," which a metallurgist of his ahility would have heen ashamed under the circumstances to overlook, sspecially after having worked the "Kustel and Hofmann process."

I am doubtful of the advantages of the Hofmann method in many cass to which Mr. Kustel thinks it applicahle. I have tried it (in ths laboratory only) on ths Murchie sulphurets, which are rather rsfractory under ths other treatment, without success, though I admit that the proof is not conclusive as it was only done once, and steam was not used in the roasting. But I have made over 20 trials of ths tailings, with and without re-roasting, hy every conceivahle "combination" of these processes, and I cannot get 50% of what they contain, yet it may he that steam roasting with low heat, in the first place, might have made a differsnce.

Touching the extraction of gold hy the Patsra process, I am at a loss to understand what Mr. Kustel meant hy his "most important diffsrence" hetween that and the Kisa. It is scarcely to he douhted that the gold in my experiment was a chloride; not the Au Cl_3 of the Plattner process, aince it was insoluhle in water, hut that lower chloride which Mr. Kustel speaks of in one of his hooks as being soluhle in the hypoaulphites, and which it is possihle to make in the frnace. It is not likely that metallic gold could he so qnickly dissolved hy sodium hyposulphite, though it may possihly he soluhle in that menstruum, as I know it to he in cyanide of potassium solution when exposed to air—and as I have read that it is in solutions of the alkalies, hut under what circumstances does the "Kiss procesa extract gold where the Patera does not?" This is the point on which several of us are anxiously awaiting "more light."

C. H. AARON.

NOTE.—My sign of interrogation was a mistake, it was meant for a sign of admiration, or rather astonishment at the weakness of the defense, and the still greater weakness of the counter attack made by Mr. Kustel, which made me think Hofmann might well cry "save me from my friends!" C. H. A.

Mr. Deetken's Answer.

EDITORS PRESS:—Not to let this Hofmann process controversy verge into a war of words, Mr. Kuatel is allowed to continue to puzzle his friends without my assistance, whether I claim its use since 1866 or 1876. Perhaps hy cleaning his spectacles he will sucoeed in unraveling the mystery so definitely expressed in my firat answer.

Mr. Kustel scouts at the idea of ever having looked at my "fixings," as he atyles my system of apparatus. Does he think there are no men of common sense who can see the wide difference hetween the apparatus in use in the chlorination works of this State, and those which existed for a short time in Europe? The largest and most skillful operatora in California differ with Mr. Kustel, and have paid me in full for my claims. But Mr. Kustel is not judge and jury in this case.

Mr. Kustel condescends to admit that he consented to puhlish my practice for the aole purpose of introducing me, the young novice, to the mining puhlic—an insolent and arrogant assertion, well knowing with what reluctance I consanted to his proposition of publication sure to he against my interest. Think of the philanthropic plagiarist, rushing to Grass Valley, paying his stage and hotel sxpsnses for ths sole and noble purpose of assisting and protecting a struggling innocent, who had made a record for himself years hefore even knowing of Mr. Kustel's existence. Shades of Emperor Norton I, redivivus, protector of innocents ahroad!

In regard to Mr. Kustsl's statement, that Mr. Beseler instructed me in the chlorine process originally, I have simply to remark that, to use a mild term, it is false.

The facts, are the following:

In the winter of 1858, Mr. Oscar Maltman, of Nevada City, and myself formed a co-partnership to erect works for ths purpose of workiug sulphurets for gold and silver by matting—the process now followed in Colorado. I give Mr. Beseler the credit of inducing me to give Plattner's process a trial at our works. The process was well-known then as a laboratory process, and described in his hlowpipe treatise. We procured a copy of the fourth volume of Kerl's Metallurgy, which gives a more detailed account of the Reichenstein practice.

I startsd in with Mr. Maltman to experiment at Nevada City, while Mr. Beseler shortly afterwards, in partnership with Mr. Ott, the old Nsvada City asssayer, tried his skill independently at Melville Attwood's mill, at Grass Valley.

We both failed to get satisfactory results. Mr. Beseler, though a graduate, as Mr. Kustsl says, of a mining academy, could accomplish no more than the polytechnic novice. Mr. Beseler got discouraged and left Grass Vallsy leaving Mr. Ott to settle hills. On my return from Washos in 1860, I took up ths subjsct again, and in connection with Mr. Maltman's energy we succeeded. These ars the facts in the case, and they can easily hs suhstantiated.

G. F. DEETKEN.

San Francisco, Feh. 10, 1880.

Another View.

EDITORS PRESS:—I have heen much intsrsstsd hy ths discussion now progressing in your paper touching the Hofmann process, which two of your correspondsnts seem to regard as unworthy the protection of a patent. Giving thsse gentlemsn full credit for honest motives, it nevertheless occurs to ms that possihly they do not take a correct view of the mattsr.

It appears that the ore on which Mr. Hofmann opsratad was auriferous, and that the gold it contained could not he extracted hy the Plattsr process "pure and simple," even aftsr ths ordinary course of preparation hy roasting, owing to ths presence of othsr mstals.

That one of thess other metals happened to he silver, also valuahle, is nothing to the purpose.

Regarding the matter in this light, the silver becomes simply an impurity, the same as the lead and zinc, tbe removal of which was necessary to ths successful applicatiou of ths Plattner process, and any means which effscted that end is a valuahle *improvement on the Plattner process.*

That this means shonld at the same time he made aubservient to another purpose, that thia one substance among several which obstructed the action of the chlorine on the gold happena to he itself a valuahle product, only provea the ingenuity of the metallurgist who hit upon so admirahle an expedient, and surely does not militate against the value of the invention any more than would tho utilization of the snlphur which ia exnelled in the roasting, and which ia also an impediment to the Plattner proceas; and it cannot he questioned that if the elimination of the sulphur, *as a means of preparing the ore for the Plattner process* were new, it would he a patentahle improvement, even though sulphurets had heen roasted hefore for other purposes, as for instance, making sulphuric acid.

METALLURGIST.

A MERITED COMPLIMENT.—A short time aince Mr. J. S. Phillips, M. E., presented to the California Academy of Sciences a copy of the new edition of his "Explorers', Miners' and Metallurgists' Companion." This heing a Californian literary production, it was given to a committee for examination. At the last meeting of the Academy, Dr. A. B. Stout reported for thia committee. He highly extolled the hook, speaking of it as in every sense a practical, carefully written treatise on the subjects to which it is devoted. He called particular attention to the soundness of the views expressed in the preliminary chapters, with relation to the formation of the earth, and to the careful and lucid manner in which the novel theories advanced hy the anthor were explained. His remarks on the more practical portion of the hook relating to assaying, prospecting, testing, etc., were highly complimentary to the author. The work as a whole heing commended as one of the few complete teohnical treatises puhlished in this State, and relating specially to the indnstry which made California what she is, was one which should he in the hands of all minera and metallurgists on the coast. Dr. Stout also highly commended the various apparatua for prospectors' use in assaying, etc., invented hy Mr. Phillips and described in the hook, he having examined the appliances and seen assaya made with them.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From Official Reports for the "Mining and Scientific Press," Dewey & Co., Publishers and U. S. and Foreign Patent Agents.]

FOR THE WEEK ENDING FEBRUARY 3, 1880.

224,121.—OPERATING GATES—H. Allen, Silverton, Ogn.

9,661.—ORE STAMP FEEDER—T. A. Cochran, San Francisco (reissue)

224,153.—VELOCIPEDE—P. L. Davis, S. F.

224,081.—AIR COMPRESSOR—W. R. Eckart, Virginia City, Nevada.

224,087.—CRUSHING AND AMALGAMATING MACHINE—L. Haight, Sonora, Cal.

224,108.—MEASURING FAUCET—W. M. Sack, Oakland.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS American and Foreign Patent Agency, the following are worthy of special mention:

HAY UNLOADER.—Jerry Tyler, Milford, Lassen Co., Cal. Patented Dec. 30, 1879. No. 223,082. The methods ordinarily employed for unloading and stacking hay and grain are: First, the employment of two-part nets, which lie in the wagon to receive the load. These nets are elevated bodily with their load by the aid of a derrick, and swung around to the place of deposit, when the fastenings are unlatched and the net allowed to part and drop the load. The second consists in connecting one side of the wagon net (which is made entire) with an unloading rope and pulleys, so that the load is rolled out of the wagon instead of being lifted, and thus much power is saved which was used in the first described method to lift the load. This method, which will serve to unload grain upon the table of a threshing machine, or upon a low platform or stack, cannot be employed to advantage in filling a barn or in building high stacks without the aid of other apparatus. This invention consists in the employment of a mast or support, having pulleys and hoisting ropes which are operated by a windlass, in combination with a continuous wagon net, which is adapted to receive the load, and which may be connected with the hoisting ropes when the wagon is brought to the barn or place of deposit, so as to roll the load up to any hight desired without undue friction or pressure upon the side of the barn or stack. In combination with this, rollers or pulleys are employed, which are connected with the inner edge of the net, and by which sufficient tension may be brought upon the net to prevent the overturning of the wagon by the action of rolling the load out. By this construction, stacks may be built with a comparatively narrow base and very high, so that they present but a small area to be protected from the weather.

STEAM GENERATOR AND SUPERHEATER.—John B. Ward, 202 Sansome street, San Francisco. Patented Jan. 27, 1880. No. 223,825. This invention relates to an improved steam generator and superheater; and the improvements consist in mounting in the fireplace of the boiler a superheating or generating cylinder or chamber so constructed as to answer either the purpose of generating or superheating the steam as desired. This chamber is so connected with the interior of the boiler by pipes that at each stroke of the piston of the engine a supply of steam is admitted to the superheating chamber, in which it spreads in a thin annular sheet in such a manner as to admit of all the watery particles being immediately converted into dry elastic steam; but before being so highly heated as to injure the valves by burning out the lubricants, it is discharged into the engine cylinder. The chamber is of a proper size to hold about as much steam as the engine cylinder will take for each stroke, and at each stroke of the piston a fresh supply of wet steam fills the space in the chamber vacated by the dry steam, which has entered the cylinder.

SULKY PLOW.—Issac Burke, Sacramento, Cal. Patented Jan. 27, 1880. No. 223,881. This plow consists in a novel construction of the axle beam or tree, which has a box or guide formed with it, so that the vertical L-shaped standard, which serves to hold the plows in the ground is acted upon directly by the weight of the machine and driver, and as it is centrally situated, it is not affected by the vertical motion of the pole. The improvement gained by the L-shaped standard is, that the standard passes up through the box upon the axle, so that while its projecting arm allows the application of the required pressure upon the plow-beam at the exact point desired, this pressure is applied directly through the axle by means of the weight of the driver and the machine.

COAL-OIL COOKING STOVE.—W. H. Wiester, S. F. Patented Jan. 27, 1880. No. 223,829. In this invention the improvements consist in the application of a single-sheet extension or heating plate to the top of the chimney in such a manner that when not in use the plate will not be heated, but when it is necessary to heat this plate to keep articles warm, the heat will be deflected so as to heat it from below without in anyway affecting the draft.

News in Brief.

A TERRIBLE famine prevails in Mesopotamia and Kurdistan.

THE United States last year sent to Europe 1,500,000 hides.

ALL the iron mines in New Jersey are being worked thoroughly.

SENATOR LAMAR has nearly recovered from his recent severe illness.

THE death of Lieutenant-Governor Chandler, of Kansas, is announced.

THE cotton crop of Brazil is estimated at 4,250,000 bales this year.

THE town of San Rafael, Lower California, has been captured by Marquez.

A SILVER mine has recently been discovered in Garrett county, Maryland.

SHAVAUX, one of the Ute "war chiefs," favors the policy of Secretary Schurz.

CAPITAL punishment is to be re-established in the Canton of Appenzol, Switzerland.

THE lead mines near Phœnixville, Pa., idle for 22 years, are now being worked.

THE College of Propaganda at Rome gives 7,000 lire for the relief of the Irish.

A RUPTURE is said to be imminent between Chile and the Argentine Confederation.

DAVID STANTON, of England, is now the champion bicyclist of the United States.

JUDGE HUNTINGTON, formerly of the Court of Claims, died recently at Hartford, Conn.

MARTIN KING fell 400 feet in a mining shaft at Bodie, Saturday, killing him instantly.

EXPORTABLE wheat in Australia and New Zealand this year will aggregate 375,000 tons.

NO appointment to succeed Indian Commissioner Hayt has yet been determined upon.

THE Supreme Court of Georgia has denied a new trial to Cox, who murdered Colonel Alston.

THE combined length of new railroads projected in this country during 1880 will be 9,000 miles.

A LAHORE dispatch announces that Mahomed Jan is re-enlisting Shere Ali's Aigindah regiments.

THE State prison of Kentucky is reported by an investigating committee to be in a shameful condition.

THE foundation of the East Beacon lighthouse, Sandy Hook, is said to be washing away.

THE investigation in regard to the colored exodus from the South is still in progress at Washington.

THE German budget places the amount of revenue and expenditure this year at 544,888,184 marks.

GEORGE W. SMILEY, of San Francisco, has been elected to the position of Chairman of the new Mining Board in New York.

IN the suit of the Government against E. J. Baldwin for alleged violation of Internal Revenue laws, the defendant was found not guilty.

THE Irish residents of San Francisco have decided to have no parade on St. Patrick's day, but to get up an entertainment, the proceeds of which are to be devoted to the relief of the sufferers in Ireland.

FRESH attractions are constantly added to Woodward's Gardens, among which is Prof. Gruber's great educator, the Zoographicon. Each department increases daily, and the Pavilion performances are more popular than ever. All new novelties find a place at this wonderful resort. Prices remain as usual.

BOUND VOLUMES OF THE PRESS.—We have a few sets of the back files of the MINING AND SCIENTIFIC PRESS which we will sell for $3 per (half-yearly) volume. In cloth and leather binding, $5. These volumes, complete, are scarce, and valuable for future reference and library use.

Mining and Other Companies.

Persons interested in incorporated shares will do well to recommend the publication of the official notices of their companies in this paper, as the cheapest appropriate medium for the same.

Atlanta Mining Company.—Location

of principal place of business, San Francisco, California. Location of works, West Tintic Mining District, Juab County, Utah.

Notice is hereby given that at a meeting of the Board of Directors, held on the Second day of January, 1880, an assessment (No. 1) of Five Cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, No. 420 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Fifth (5th) day of February, 1880, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Friday, the Twenty-Fourth (24th) day of February, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

A. F. McGREW, Secretary.

Office—Room 7, No. 420 Montgomery street, San Francisco, California.

POSTPONEMENT.—The delinquent day of the above named Company is hereby postponed until Thursday, February 26th, 1880, and the day of sale to Monday, the 29th day of March, 1880. By order of the Board of Directors.

A. F McGREW, Secretary.

Office—Room 7, No. 420 Montgomery street, San Francisco, California.

Butte Hydraulic Mining Company.—

Location of principal place of business, San Francisco, California. Location of works, Butte County, Cal.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 2) two levied on the Thirty-first day of October, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Certificate.	No. Shares.	Am't.
E Poirson	13	2½	$25 00
L Lapierre	22	2½	25 00
H Marcoux	24	2½	25 00
J B Lussier	25	2½	25 00
John Britt	20	2½	25 00
Geo W Deitzler	37	5	50 00

And in accordance with law and an order of the Board of Directors made on the 31st day of October, 1879, so many shares of each parcel of such stock as may be necessary will be sold at public auction at the office of the company, room 3, No. 220 Sansome street, San Francisco California, on Monday, the 22nd day of December, 1879 at the hour of 10 o'clock A. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

L. L DENNERY, Secretary.

Office, room 3, No. 220 Sansome St., San Francisco, Cal.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock of the Butte Hydraulic Mining Company is postponed to the Fifth day of January, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock is postponed to the second day of February, 1880, at 10 o'clock A. M.

L. L. DENNERY, Secretary.

San Francisco, Cal., January 3d, 1879.

POSTPONEMENT.—By order of the Board of Directors the above sale of delinquent stock is postponed to the Sixteenth day of February, 1880.

L. L. DENNERY, Secretary.

San Francisco, February 2nd, 1880.

California and Oregon Land Company.—

Principal place of business, San Francisco, California. Location of works, Lake and other counties, Oregon.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 5th day of February, 1880, an assessment of Thirty cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary.

Any stock upon which this assessment shall remain unpaid on the 15th day of March, 1880, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Thursday, the 15th day of April, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale.

R. N. VAN BRUNT, Secretary.

Office, 313 Pine street, room 6, San Francisco, California.

Cataract and Wide West Gravel Mining

Company. Principal place of business, San Francisco, California. Location of works, Eho Mining District, Calaveras County, California.

Notice is hereby given that at a meeting of the Board of Directors, held on the 2nd day of February, 1880, an assessment (No. 2) of Twenty-five cents (25 cts.) per share was levied upon the capital stock of the corporation, payable immediately in United States gold and silver coin, to the Secretary at 26½ Kearny street, San Francisco, Cal.

Any stock upon which this assessment shall remain unpaid on the 8th day of March, 1880, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Monday, the 29th day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. B. LAKE, Secretary.

Office, room 18, 26½ Kearny Street, San Francisco Cal.

Gila Silver Mining Company.—Location

of principal place of business, San Francisco, California. Location of works, Reveille Mining District, Nye County, Nevada.

Notice is hereby given that at a meeting of the Board of Directors, held on the 15th day of January, 1880, an assessment (No. 6) of twenty-five cents per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, room 7, Safe Deposit building, 328 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the Seventeenth day of February, 1880, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the Ninth (9th) day of March, 1880, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.

WM. W. PARRISH, Secretary.

Office—Room 7, Safe Deposit Building, No. 328 Montgomery street, San Francisco California.

Gover Mining and Milling Company.—

Location of principal place of business, San Francisco, California. Location of works, Amador County, near Drytown, California.

NOTICE.—There are delinquent upon the following described stock on account of assessment (No. 40) levied on the Twenty-fourth day of December, 1879, the several amounts set opposite the names of the respective shareholders, as follows:

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade

SAVE YOUR GOLD!

Highly Important to Miners and Quartz Mill Men!

SILVER PLATED AMALGAMATING PLATES.

The best process yet discovered for saving fine or float gold. Extensively used with great success in gravel and quartz mining in various parts of the Pacific Coast. Over one thousand orders have been filled, and the demand is constantly increasing. Old Mining Plates bought or taken in exchange for new Silver Plated Plates. Gold extracted from old Plates at a moderate cost. Old Plates (which often contain a surplus of gold above the cost of plating) can be re-plated.

With the most extensive facilities on the Pacific Coast, orders can be filled very promptly and satisfaction guaranteed. All kinds of metal goods plated. Send for circular.

SHEET IRON PIPE.

SUB-IRRIGATION.

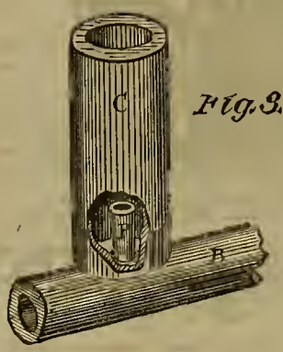

Fig. 3.

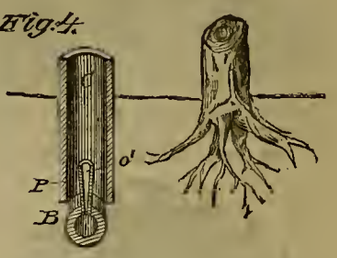

Fig. 4.

—FOR—

Orchards, Vineyards, Small Fruits, Alfalfa, Lawns, Vegetables, Etc.

The Asbestino System consists in conducting the water in concrete pipes laid below reach of the plow.

It saves from three-fourths to nine-tenths the water used in surface irrigation.

It is under perfect control, and can be applied wherever irrigation is needed.

The surface remaining dry there is no need of Summer Cultivation, either before or after irrigating.

The soil is never excessively wet *and cannot bake*, but remains moist, loose and at a nearly uniform temperature, promoting a long-continued Summer's growth.

Anything which the soil lacks as plant food (manure, lime, etc.,) can be easily, directly and economically applied in liquid form; the pest of the vineyard—phylloxera—can thus be easily reached.

No grading is necessary, as the system works perfectly on hillsides and undulating land.

Roots *cannot* get into the pipe, neither can it *suck mud*—difficulties never overcome by any other system of sub-irrigation.

The pipe is made continuously with a recently patented machine which *makes and lays* it in the trench, following all the undulations and curves.

Water is not kept in the pipes; but is applied about twice a month.

Three men will easily lay 1,200 feet of two-inch pipe in 10 hours.

This system and machines used are fully protected by U. S. Patents.

Our pipe machine makes the cheapest and best tile drain known, and is especially valuable for making and laying pipe for conducting water from springs, out of canyons, etc.

For further information, circulars, etc., address WILSON & BROWER, General Agents for California, Sacramento, Cal., or

Asbestine Sub-Irrigation Co.,

Los Angeles, Cal.

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Ahsolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access ohtainahle to all the valves hy removing air chest covers. Entire ahsence of springs or friction to open or shut the valves. No valve stems to hreak and drop inside of cylinders.

Have no back or front heads to hreak. The only Machine that makes a perfect diagram. No expensive foundations required. Ahsolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of ahont 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

N. W. SPAULDING'S

PATENT DETACHABLE TOOTH SAWS,

Manfuactory, 17 & 19 Fremont St., S. F.

OF IMMENSE PRACTICAL VALUE TO EVERY SAW USER.

GRIMSHAW on SAWS!

History, Development and Actlon; Classification and Comparison; Manufacture, Care and Use of SAWS of all kinds. Large Octavo. Over 153 Illustrations.

By ROBERT GRIMSHAW, Ph. D.,

Member of the Jury on Wood-working Machinery at Paris Exposition of 1878.

This thorough work, impartially written in a clear, simple and practical style, treats the Saw scientifically, analyzing its action and work, and describing, under the leading classes of Reciprocating and Continuous Acting Saws, the various kinds of large and small hand, sash, Mulay, jig, drag, circular, cylinder and band Saws, as now and formerly used for crosscutting, ripping, scroll-cutting, and all other sawing operations in wood, stone and metal, ice, ivory, etc., in this country and abroad. With appendices concerning the details of manufacture, setting, swaring, gumming, filing, etc., tables of gauges, log measurements from 10 to 24 feet, and from 12 to 96 inches, lists of all U. S. Patents on Saws from 1790 to 1880, and other valuable information. Elegantly printed on extra heavy paper, wide margin, copiously indexed

Owing to an increase of nearly 100% in number of pages and illustrations since first projected, the subscription price is this date made $2.00, postage paid, up to date of publication, after which time full retail price will be charged. In press Orders received now at subscription price, $2.00.

ROBERT GRIMSHAW,
624, 626 and 628 Market Street, Philadelphia.

FIXTURES and FURNITURE,

For Sale.

(Established 12 years in San Francisco; now going East.) Apply at first to X. Y. Z., thie office.

This papar is printad with Ink furnishad by Chas. Enau Johnson & Co., 509 South 10th St., Philadalphia & 59 Gold St., N. Y. Agent for Pacific Coast— aaph H. Doraty, 120 Sutter St., S. F.

GIANT POWDER

MANUFACTURED UNDER A. NOBEL'S ORIGINAL AND ONLY VALID NITRO-GLYCERINE PATENTS

Nos. ONE, TWO and THREE.

Stronger, Better and Safer than any other High Explosiva.

Judson Powder

IS NOW USED IN ALL LARGE HYDRAULIC CLAIMS.

It breaks moro ground, pulverizes it better, saves time and money, and is superseding the ordinary powder wherever it ie tried. Triplo Force Caps and all Gradee of Fuse.

BANDMANN, NIELSEN & CO.,

Scientific Press

Patent Agency.

[ESTABLISHED 1860.]

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have ahle and trustworthy associates and Agents in Washngton and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Lihrary, and record of original cases in our office, we have other advantages far heyond those which can he offered home inventors hy other Agencies. The informatiou accumulated through long and careful practice hefore the Office, and the frequent examination of Patents already granted, for the purpoee of determining the patentahility of inventions hronght hefore us, enahles ns often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 202 Sansome St., S. F.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

VULCAN BLASTING POWDER.

The Strongest, Safest, Most Uniform and Reliable "HIGH EXPLOSIVE" Manufactured on the Coast.

MINERS TESTIFY THAT IT IS FREE FROM OBJECTIONABLE FUMES.

We call the attention of all desiring such a Powder to our various gradee, which we are prepared to sell at LOWEST RATES.

No. 1.—Equalling Liquid Nitro-Glycerine in Strength. We recommend thie Grade in extremely hard rock, boulders, iron, etc.

No. 2.—Will do the work thoroughly in all hut the hardeet kinds of rock.

No. 3.—For bench work, pipe-clay, eoft and ehelly rock, outside work and quarrying.

Singla and Tripla Forca Caps, Fusa of all Gradaa, Vulcan Powdar Thawing Boxaa, Battariaa and Exploders, For Sala at tha Lowast Rataa

VULCAN POWDER COMPANY,

Office, 123 California Street, Rooms 25 and 26, - - SAN FRANCISCO, CAL

LAKEPORT, Lake Co., Cal., Nov. 2d, 1878.

MESSRS. DEWEY & CO.—*Gentlemen:*—I hereby acknowledge receipt of patent, for which please accept my sincere thanks. When I have any further buciness in this line I shall certainly employ you. With kind regards, I am, Yours very truly, CHAS. SLATTERBECK.

Mining Books.

Orders for Mining and Scientific Books in general will be supplied through thie office at published ratee.

A. S. HALLIDIE.

Office, No. 6 California Street,

SAN FRANCISCO.

Manufacturer and dealer in all kinds of

Iron and Steel Wire Rope,

Flat and Round, for Mining, Shipping, Hoisting and General Purposes.

Having the most complete and extensive Wire Rope Works in the United States, I am prepared to manufacture Wire Rope and Cables of any length or size at short notice, and guarantee the quality and workmanship equal to any made at home or abroad.

Iron, Steel and Galvanized Wire

Of all Sizes on hand or made to order.

Barbed Fence Wire.

Sole Proprietor of

Hallidie's Endless Ropeway,

For the Transportation of Ores, Etc.

Send for a Circular.

VOLUME XL Number 8.

Needed Reforms in Mining Matters.

We need a definite legal decision as to the true definition of those mining terms which are now so vague as to admit of various conetructions heing put upon their meaning. We douht if any one can define the legal differcnce hetween "veins," "lodes" or "ledges;" or "dips," "spurs," "variations" or "angles;" or even hetween "locations" and "claims." If a man has located a "lode, vein or ledge," he oertsinly has a "claim" to the "location." True, in the "jnmping" procedure, it very frequently occurs that the jumper "olaims" the property upon which he has never msde a "location." With the vagueness of the ahove terms thero arises a confusion in different mining districts as to their correct application, which not only gives rise to quarrels among the locators, hut frequently forces them into expensive litigation. The courts have from time to time endeavored to eetahlish a fixed meaning to some of these terms, hut as the decisions of different courts have not been uniform, the matter still remains as duhious as ever.

Another needed reform in mining operation is that of a decided reduction in office expensee. The New York mining company have taken the lead in this direction, and have reduced the salaries of all officers one-half. They have also required the President and Secretary to give honds for the faithful performance of their duties. This is in strict accordance with husiness and economical principles, and is a safeguard to the stockholders against loss through the malfeaeance of these officers. Honest men are willing to he watched; dishonest ones need to he so. The more economy is practised in expenditure, the less amonnt the stockholders will have to advance as assessments. Still there is a line heyond which economy merges into parsimony. It is not always the superintendent who is willing to work for the lowest wages that is the cheapest in the end. To he worth anything in the direction of the work in a mine, he should he a man of practical experience hoth in directing the mining and in governing his men. With these reqnisites fully developed, he should he paid fair and liheral wages. Upon him depends, in a great measure, the success of the mine, and if any one of the officers should receive a good salary, he shonld he the one. He has to be on hand day and night. If any nntoward event occnrs in the mine, he is looked npon hy the men as the one who will lead them to overcoming the difficulty. Wherever he will lead, he will always find stout hesrts and sturdy hands to follow and ohey his instructions. As a general rule the President receives the highest recompense. And yet he performs the lightest duties of any of the officers. He goes to the office at his leisure, sits in a comfortahle chair, reads the letters from the mine and the daily papers, goes out for an hour or more to indulge in a lunch, and after that, if the weather is pleasant, spends a portion of his salary in a ride behind a fast team, and closes his arduous duties hy partaking of a luxurious dinner and going afterwards to the opera or theater. He is never called up at midnight to go hundreds of feet nnder ground and work and etruggle to secure a caving level or shaft. If the pumps get out of order he doee not have to etand in the rising water to ohviate the difficulty. The hardships and the responsihilities of the Superintendent are unknown to him. It is in the adjustmeut of wages to the nature of the duties performed that a reform is needed.

An attempt was made on Tuesday last to kill the Imperial family at St. Petersburg, hy exploding a mine in the Winter Palace immediately under the dining hall. Owing to an accidental delay, none of the Royal family were in the hall at the time of the explosion. Five soldiere were killed and 35 wounded.

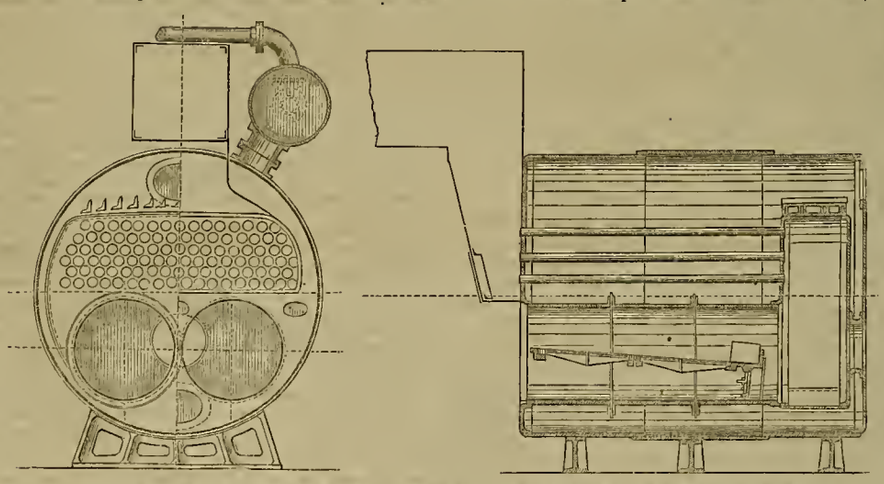
Prescott, Scott & Co.'s Horizontal Boilers.

The accompanying engravings represent a form of horizontal hoiler, with internal furnace and return flues, made hy the Union Iron Works of this city.

The hest American charcoal hammered iron and lap-welded tuhes are worked up in the construction of these boilers; and they are recommended where it is necessary to do away with the ordinary hrick work. They are compact, readily accessihle in all their parts, economical in point of fuel, es, the furnace heing snrrounded hy water, no heat can he lost hy radiation, they will gonerate steam with great rapidity, and can he set np or taken down with little trouhle. Everything is furnished to make these hoilers complete in every particular, such as eafety valves, steam and water gauges, hlow and gauge cocks, etc., etc.

They are made in eight sizes, from 54-inch diameter, 8 feet long, with 230 square feet of heating surface, and weighing 4,915 pounds, up to 90-inch diameter, 10 feet long, with 850 square feet of heating surface, and weighing 15,000 pounds.

Utility of a Babcock Extinguisher. — We have bad a small Bahcock fire extinguisher standing guard on a shelf near the hall hetween our editorial and the press and composing rooms for the past ten years, hut never had occasion for its services during all that time until this week. On Tuesday, a coal-oil stove, which was placed on the floor near the ink fountain of the press, to make the ink dietribute more freely on a cold morning, caught fire and hlazed np to the ceiling. The press room contained several tons of paper in its original packages and a great quantity of other paper stock. The cry of "fire" sounded through the huilding, and the alarmed occupants of the printing office eoon crowded around, looking in a seemingly helpless manner at the increasing flames. A large conflagration was certainly imminent. Suddenly one man thought of the extinguisher and hrought it in. It was no sooner put in use than the burning oil was extinguished in an instant. We have never hefore fully appreciated the advantage of this little appliance, hut in this case it no douht saved several thousand dollars' worth of property. "That press-man of ours" nses coal-oil stoves no more.



HORIZONTAL BOILERS, WITH INTERNAL FURNACE AND RETURN TUBES.

The numher of foreign immigrants who arrived at the port of New York during the year 1879 was 138,945, against 81,505 during 1878, an increaee of 57,440, or 70.5%. The increase during the last quarter was at an evcn greater rate, the numher of arrivals in that portion of last year heing 40,749, against 17,208 in the last three months of 1878, a gain of 23,541, or 73.1%. This shows that the great stream of humanity that pours into this new land is rapidly increasing in volume. There is room yet for millions more.

Placer County Quartz Mines.

In oonversation with a gentleman who has recently visited Placer county for the purpose of examining certain quartz mines, we learn that there is considerahle prospecting going on, and that quartz intereets are looking np. Mining still constitutes one of the leading features of this county, although its foothills oontain many thriving vineyards and gardens, and its fruit trade is very considerahle. It is well furnished with railroads, and has an industrious permanent population.

The Julian mine, one mile from Newcsstle, will have its new 20-stamp mill, with four Frue concentrators ready to run on $14 rock hy the first of March. The Superintendent is Mr. DuBoie, formerly in charge of the Extra mine, Copper City, Shasta county. The Julian was recently purchased hy New York parties for $200,000. The mill will run hy a hurdy-gurdy wheel, with 140 feet fall of water from the Bear River ditch. The shaft is down 700 feet.

The Decker mine, hetween Auhurn and Newcastle, is getting out ore running from $12 to $15 per ton.

The St. Patrick mine is running 15 stamps on what is supposed to he high-grade ore.

Prof. Price and Supt. Roherts of the Rock Creek and Auhurn mine have heen carefully examining the property looking to the adviea-hility of putting up a 20-stamp mill. Water power can be ohtained from the Bear River ditch.

San Francisco Microscopical Society.— The annual meeting of the San Francisco Microscopical Society was held on the 5th inst., when the following officers were elected for the ensuing year: C. Mason Kinne, President; Wm. Morris, Vice-President; Charles H. Dunnison, Recording Secretary (re-elected); Charles W. Banks, Corresponding Secretary (re-elected); G. L. Murdock, Treasurer (re-elected). The report of the retiring President, Henry C. Hyde, was an elahorate review of the work of the society during the year. The Treasurer's report showed the finances to he in fair condition, yet desiring improvement for future operations. The Lihrarian reported that the library consisted of 500 volumes of selected scientific works and was, without dispute, the heet collection of its kind in the State. The cahinet contained ahout 4,500 slides of mounted specimens.

The law prohihiting corporatione from employing Chinamen having taken effect, the East Oakland Jute Factory Company knocked off the seven hundred and ninety Chinamen employed in the factory and shut down for the present.

The German Reichstag have elected Count Von Arnim Baytenzherg President of the Chamher.

California Trade-marks and Labels.

A hill has been introduced in the California Legislature, ohviously to protect lahels and trade-marks, hnt no douht indirectly aiming at Chinese manufactured goods. It provides that it shall he unlawful for any corporation, company or individnal to sell or expose for sale any goods, wares or merchandise of any description whatever, in whole or in part under false signs, lahels, cards or placards. Violation of the provisions of the act is to he considered a misdemeanor and punishahle with fine or imprisonment.

This is the first time, to onr knowledge, that any attempt has heen made in this country to punish hy imprisonment and fine an infringement of patent or trade-mark. In Germany the government guards the rights of inventors in this way hy imprisoning for infringement. Here damages may he ohtained, if the infringer has anything which can he levied on; if not, he goes scot free.

The hill, if it hecomes a law, will he more apt to hring work to the lawyers than to accomplish any great result. In the first place, the question of infringement "in whole or in part" of lahels, cards, etc., is one which will he difficult to decide. In the next place, onr laws on the suhject of trade-marks, lahels, etc., are at such loose ends that the qnestion of ownership of a trade-mark will he difficult to estahlish.

Since the trade-mark law of the United States was declared unconstitutional, we are dependent on State laws for protection. While they are well enough in their way so far as they go, they do not go far enough. The law provides that trade-marks, lahels, etc., may he registered on payment of a certain fee tc the Secretary of State for euch registration. All he has to do is to file them away and pocket the fee. He does not examine the mark, makes no examination of its novelty; hut simply givee a certificate of registration. It is none of his hnsiness whether it infringes some one else's mark or not, the law making no provision in this respect. There is, therefore, no reason why a dozen people should not register the same mark, one after another, and each receive a certificate giving them the exclnsive right to nse it. The Secretary of State has no authority to withhold a certificate, provided the applicant prepares his papers according to rule. With the U. S. government law, examinations as to novelty were made and there was some protection; hut with our State law, as it now stands and ie carried out, great confusion will eventually result.

It seems to us hetter that our present laws should he remodeled, so as to he of practical utility, rather than new ones should he made while the defects of the old still remain. If some of our legislators would examine into the workings of the present law they would see the justice of our remarks.

Discharge of Chinese Miners.—C. Palache, of the firm of H. C. Newhall & Co., local agents of the Great Western Quicksilver Company of Lake county, gives the following particulars of the discharge of Chinamen hy that oorporation and its effects upon the white people there: "The total numher of Chinamen employed was 200, and of white men 21. The Chinese received from 80 cents to $1.25 per day, the minere receiving $1. Following the discharge of the Chinese was that of the whitee, as the price of their lahor was from $2 to $2.50 per day, and the employment of more white lahor at those prices would not permit the company to carry on its husiness with profit. Of the white lahorers, 14 were married and had families, and the 30 children helonging to the little settlement gave employment to a echool teacher and caused the erection of a school house, which will now have to he closed, the worke having been ehut down."

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Manufacture of Copper.

Editors Press:—I have noticed lately several articles in your valuable paper on the subject of copper emelting on the Pacific coast, and coneider the subject worthy of mature and deliberate consideration, as being of great interest and importance to the people of this section.

There is, no doubt, a sufficiency of raw material obtainable from the Pacific States to more than supply our wants in copper in its various manufactured forms. Why then should we send the raw material to England or the Atlantic States, pay high freight on same and on its return in manufactured shape, besidee paying large profits for manipulating the same, while tbie may be done at our doors, thus giving employment to scores of workmen aud retaining within ourselves the money paid on freights and to Eastern manufacturers? It may be said that we cannot compete with the Eastern States in the manufacture of copper. This would be true, provided we had to supply the raw material from distant localities; but fortunately we have the material at home, and I etate positively that the difference in the cost of manufacture on this coast, owing to increased cost of fuel and labor, will be more than counterbalanced hy the freights paid on the manufactured article from the Eastern manufactories to this point. Another objection often made ie that copper smelting has proved a failure hoth in this city and in the State at large. Some years ago, it is true, an attempt was made to reduce copper ores in this city by a *new process*, and proved a failure financially, as any one having the slightest knowledge of the reduction of copper could have predicted. The "new process" was a complete failure, although a small quantity of refined copper wae made by the "old method" fully equal in quality to the hest "Lake Superior Ingot." As the establishment referred to was put up solely to work copper ores hy the "new method," its failure cannot be considered as bearing on the practicability of copper smelting by the old and tried methods.

Another objection offered is that the market for refined copper on the Pacific slope is too limited to justify the erection of reduction works and rolling mills on a large scale. I have no statistics at hand to refer to, hut preeume that there is a considerable consumption of copper annually on this coast, and more or less is exported to China and Japan, which countries could no doubt be snccessfully supplied by the product of a manufactory ovcr the local demand. These countries being much nearer to us than to New York, we could euccessfully compete with Eastern manufacturers, as the difference in freight would be two to three cents per pounde in our favor, besides the eaving of three to four weeks' time in shipments. The writer well remembere the time when all the copper ores mined in the United States and South America were ehipped to Swansea for reduction, and the refined and manufactured copper bought in that market for consumption in this country.

Some 40 years ago eome capitalists in Baltimore ventured the reduction of copper ores at that point, and the enterprise proved a decided euccess, returning to the promoters a rich return on their investment. This establishment has continued in successful operation to this day, and is a large purchassr of copper ore hoth in the United States and South America.

The time is not far distant when the capitalists of this coast will make a similar investment, with like results. It is unnecessary at the start to employ a very large amount of capital in this enterprise, but as ore in sufficient quantity could not he procured near the city, more capital would be required than otherwise would he the case, as low-grade ores would have to be beneficiated hy smelting at the mines to admit of shipment for final treatment in this city, and hence a considerable sum would he invested in preliminary emelting plant. Most of the ores sent to this city for re-shipment to England or Baltimore coutain 25%, or more, of copper, and is sold here at $2.50 for each unit of percentage, or, say, for 25% ore, $62.50 per ton of 2,000 pounds, a deduction being made from the humid assay of the ore of 1 3-10%, which deduction amply covers loss of metal hy the manipulatiou of the ore. The price paid for ore, of course, varies, fluctuating with the price of refined copper; the ahove figures are hased on refined copper at 25½ cents per pound, the present price. At the above rate, the smelter pays for the copper in the ore at the rate of 12½ cents per pound; the cost of reducing ores of 25% to fine copper will not he over 4½ cents per pound, all told, making the cost of the refined copper produced from the ore 17 cents, leaving a margin of 8½ cents per pound, at present price of the metal. Ae hut a emall quantity of 25% ores can he had in the city, it would be necessary, in order to insure an ample supply of material, to have in favorahle localities one or more furnaces to beneficiate, by emelting, ores of a lower grade than could be profitably ehipped to the city in its raw state, the product of such beneficiation being either crude or "black copper" of 80% purity, or regulus, or "matte," of, say, 50%. There are many mines in this and the adjoining States, which can produce a coneiderahle quantity of 10% to 15% ore, hut which yield little or no ore of sufficient grade to pay for shipment. These low-grade ores could no douht he hought at the mines for $1 per unit of copper, or $10 to $15 per ton. The copper in the ore, at the ahove rate, would cost the smelter 5 cents per pound; $10 per ton, or 5 cents per pound of copper, will reduce the ahove to either "hlack copper," or "regulus," as previously mentioned. The cost of the copper in this product will be 10 cente per pound; an additional 5 cents per pound is ample to cover freight and the cost of refining the "black copper," or "regulus," makiug the cost of refined copper 15 cents per pound, leaving a margin, with copper at 25½ cents, of 10½ cents per pound.

An outfit for the smelting of low-grade ores, as above specified, would consist of a 25-horse power eugine with boiler; a No. 5 "Baker blower," a Blake crusher and a water-jacket hlast furnace, together with a few rough huildings; a complete outfit for the reduction of 50 tons of ore per day to "regulus" or "black copper" would cost not to exceed $10,000.

The refining worke, located at or near the city, of a capacity of five to eight tons of refined copper per day, would consist of a 30-horse power engine and boiler, a Blake crusher, one large reverberatory calcining furnace, two roasting furnacee for making "blister" or "pimple" copper, one refining furnace, one water-jacket blast furnace, one blower with a substantial building 200x50 feet in dimensions. Such a plant would cost from $40,000 to $45,000.

A copper rolling mill is very costly—an immense amount of machinery is under ground and out of sight, the foundation for and part of the working gear of the immense rolls used.

An establishment for rolling four tons of copper per day, into sheets or bars, would consist of an engine and boiler of 250-horse power; two pairs of "hreak-dowu rolls;" two pairs "finishing rolls;" two pairs "bolt rolls;" one pair large rolls; two pairs yellow metal rolls; eight anpealing and heating furnaces; five pairs shears; one furnace for making "yellow metal" (hrass); one set of stamps for stamping kettle bottoms, and one "tinning department"—the whole outfit complete costing from $13,000 to $14,000 for each pair of rolls, or, in all, from $120,000 to $130,000.

Tbe cost of rolling in the East for all kinds of orders averages about three cents per pound; the same work may cost on this coast three and a half to four cents per pound; the differcnce in the price of manufactured copper is often ten to fifteen cents per pound. The loss of copper by wastage in mauufacturing does not exceed eight pounds to the ton, or four-tenths of one per cent.

Franklin Farrell, of the Farrell Foundry and Machine Works, Ansonia, Conn., is the hest copper mill builder in the United States, the company of which he is the head making a specialty of the manufacture of copper rolling machinery.

I trust this article may be of some interest to your readers, and hope that this suhject may receive the attention it merits.

John Williams.

San Francisco, February 10, 1880.

Mineral Ranges of Beaver County, Utah.—There are four distinct mineral-bearing ranges in Beaver county. The Granite range heing on the east side of Beaver valley, up which the Utah Southern is being built, in which is situated the Cave mine, Coral Reef, Richmond, Old Lead mine, Jolly-Boy and many othere. Then comes the Star range, easy of access, lying on the west side of the valley, with Rocky and Beaver Lake districts lying on a line aud only broken by two washes or natural passes for railroad or wagon roads to Frisco, the headquarters of the Horn Silver mine. Then comes the San Francisco range, ahout 10 miles long, 12 miles from Star district west and 16 miles from Milford, in Beaver valley, the proposed junction of the Frisco branch of the Uuah Southern, from which the locomotive to Frisco will have to climb 1,600 feet, that being the altitnde ahove Milford, but on an easy and gradual grade up the grand wash to said burg. The Wah Wah range, 12 miles west of the San Francisco range, is about thirty miles long and forms the boundary of Utah and Nevada. In this range is situated Pine Grove district. It is also the home for saw mills and charcoal camps, for it is in this range that Lamersdoffville is sitnated, with Charles Lamersdoff as the hishop of the stake. All these ranges show, today, numerous outcroppings of valuable metals, upon which comparatively little work or prospecting has been done. The discovery of the Horn Silver mine did considerahle to encourage prospecting and further developments, hut the past low price of lead and long and slow transportation which we have had to endure have seriously retarded the development of good mining claims in thie county and all through southern Utah.—*Salt Lake Tribune.*

A Curious Find.—While a miner was at work on the 385-foot level of the Standard mine, pickiug in some rather hard ground, there rolled out and fell at his feet a fossiliferous rock, which is quite curious. One side is perfectly smooth and leaves the impression of a broad-leafed fern. The formation is perfect and slightly raised out of the smooth surface, which has a rather bluish color. Here is something for the scientific man to explain. To find a vegetable fossil in ground of euch a character is something unusual.—*Bodie Free Press.*

Changes in Plant Life on the San Francisco Peninsula.

The following essay, which will he of interest to all botanists and observers of plant growth generally, was read at tbe meeting of the Academy of Sciences, February 2d, by Dr. Herman Behr of thie city:

We are not very apt to notice changes that gradually and progressively prepare themselves in our surroundings. We have no room in our journals for facts of every-day occurrence, and at the same time these gradual changes offer more analogiee to the great secular changes that have preceded the present state of our glohe, and give more material for the study of evolutions than all floods, earthquakes and other cataclysms.

All vegetation of our earth is suhject to secular changes, and it is not necessary to go to the fossil plants, imbedded in coal, to find ample proofe for this axiom. The bogs of northern Europe, the lacustrine dwellings of tbe alpine regions, show in different strata the remainders of different forest trees; and in the Atlantic States many acute observers have noticed that the birch gradually supersedes the conifers.

Such a process of change of course is accelerated, if to the secular procese of change is added the powerful agent of human activity. I have had the good fortune to witness this process in two different quarters of the globe; in Australia and in Californuia.

The neighhorhood of San Francisco and its flora in the year 1850 was not entirely iu its natural state, but still the three original types of landscape that constituted the regiou could well be distinguished. The sand-dunee and hills were covered hy a dense chapparal of live-oak (*Quercus agrifolia*), *Ceanothus thyrsiflora*, and on northern well-moistened declivities hy buckeye trees (*Æsculus Californica*). In some localities a wild cherry (*Prunus ilicifolia*) entered this combination, but was in growth and foliage eo little different from the other components that it easily escaped notice.

This whole region grew very little grass, a fern (*Pteris aquilina*) forming a kind of a rough and rathor transparent turf. With tbe exception of a *Scirpus*, even on marshy places no Cyperaceous plaut was growing. *Achillea*, *Millefolium*, *Baicharis*, *Solidago*, *Scrophularia* and *Mimulus*, distrihuted in tufts, varied the otherwise naked ground. The depressions of this formation frequently contained marshes with a shruhhy vegetation of currant bushes (*Ribes malvaceum*), and gooseherries (*Ribes Californicum*) and a herbaceous vegetation of *Helenium*, *Baicharis* and *Mimulus*.

This character of vegetation reached almost without any modification up to the Mission Dolores, where grassy plains and hills, containing arborescent growths only in their ravines, took its place. A belt of the same formation extended from North Beach to the Presidio, interrupted here aud there by the *Artemisia* and *Franseria*, vegetation of the moving dunes and the seashore.

The character of this open tract was in no way different from that of the common California pasturage ground when its vegetation is not yet too much interfered with. A turf, mostly of annual grasses, whose monotony relieved by frequent patchee of *Nemophila* and *Eschscholtzia*, is interwoven with different species of *Sanicula*, *Orthocarpus*, *Castillega* and *Lupinus*, the latter in their arhorescent species frequently forming miniature forests.

The third formation of landscape was the most characteristic, and many of the component parte of its flora have entirely disappeared from our neighhorhoods; one of them, an *Arenaria* of eingular beauty, probably is extinct; at least has not yet been found again in any other locality.

This formation occnpied the southern part of the peninsula, and consisted of a large marshy plain, merging towards the sea into the common California marsh full of meandering, brackish creeks and separated on the other side from the ceanothus and live oak, and chapparal by a densely interwoven and much varied arhorescent vegetation, where the trees of the chapparal mingled with *Myrica*, dogwood (*Cornus*), honeysuckle (*Lonicera*), *Garrya*, hay tree (*Oreodaphne*), *Photinia*, etc. A corresponding herbaceous vegetation of luxuriant *Megarrhiza*, hemlock, *Heracleum*, different species of *Rumex*, *Polygonum*, and three gigantic species of *Aspidium* covered the hlack and yielding ground.

After having penetrated this helt, you wonld euter a boggy prairie, in which stripes of the above-mentioned arhorescent vegetation indicated the more elevated points and ridges.

The vegetation of the prairie itself was a most anomaloue one, considering the latitude and the merely nominal elevation above the level of the sea. It was a spec of the Arctic flora. Out of a mossy surface rose the slender culmi of a *Festuca*, mixed with *Carex* and *Eriophorum*. The characteristic *Menyanthes trifoliata* showed everywhere its feathery racemus; at present, when you wish to see them, you have to go to Alaska or to very considerable mountain elevatious.

Besides these was growing a *Habenaria*, and the *Epipactis gigantea*, two Orchideous plants.

Angelica, *Heracleum*, *Oenanthe*, *Hydrocotyle* and *Nuphar* represented a vegetation which can he studied etill in some localitiee of this peninsula, hut not in such vicinity of the city.

Wherever the moisture formed a surface it was immediately covered by tbe graceful *Azolla Caroliniana*, a *Bidens* and the *Arenaria* ahove mentioned that has not yet heen found again.

Now the first-mentioned type of vegetation, the chapparal, exists still in some fragments in the Presidio reservation; the second, that of the pasture land, is to he met with still, wherever the distance from the city is considerable enough to protect native vegetation; hut the third type has entirely disappeared.

We now come to the causes. It is not only the quick growth of the city, the sudden change of grade, etc., that have disturhed the original equilibrium in nature; for there still exist lonely, neglected places enough in the immense circumference of the city, where an original vegetation could have remained undisturhed and where it was protected even against the attacks of domestic animals.

By comparing the present flora of the surroundings, we shall easily recognize one of the most powerful agents in the destrnction of original vegetation. At present tbe three original types of landscape are no more distinguishable. The improvements of a growing city have brought all to the same level. The original arborescents have been cut down partly for fuel, partly to make room for houses. Horticulture has replaced them hy the conifers of our Sierra and the evergreene of Australia.

The vegetation of the peuinsula ie at present more Australian than Californian, and if it was not for the heauty of our sequoias, pines and firs of our mountains, scarcely any California tree would have found admission.

Parallel with this artificial immigration of Australian arhorescents, goes an herbaceous immigration from Europe and Africa.

Our original vegetation has very little power of resistance. Its very variation is a proof of a certain want of vitality, for any more vigorous organization, by superseding the weaker ones, would have produced originally the monotony developed at present by the immigration of foreign plants.

First of all I mention *Silybum Marianum*, a native of the Mediterranean region, observed hy me the first time in 1854 in California, in 1848 in South Australia. Wherever it gets a hold of the soil all native vegetation disappears. California is not the only land invested by tbis thistle. I have witnessed the same invasion in South Australia, and have read the statement of my former teacher, Prof. Burmeister, at present in Buenoe Ayres, that the same thistle protects, through the time of its vegetation, the settlers against inroads of the Pampas Indians, as eveu there wild horsemen cannot cross the immense thickets formed hy the same species of thistle.

The influence of this weed ie not confined to the neighhorhood of San Francisco, and it is chiefly the miniature forests of Lupinee that suffer from its invasion.

Another weed, *Cotula coronopifolia*, does the same work in moiet ground that ie hegun by Silybum in the more arid tracts of soil. The plant, a native of Southern Africa, was observed for the first time by me in 1854. I also have witnessed its invasion of South Australia, and I recollect very well the single specimen I found near Adelaide in 1845. It is well known in Mediterranoan Europe, but as to the date of ite invasion, I only know that it was common there at the same time when I found the first specimen in Australia. This weed has transformed the varied aquatio vegetation of the different places invested by itself into one monotonoue green mass with yellow buttons. Our gracefnl water fern, *Azolla*, that formerly ornamented abundantly our creeks hy its floating turf, is scarcely to be found any more.

Now, hoth of these plants which could he called "the coming plants," are Syngenesists or Compositæ. The Compositæ themselves are characteristic of the most modern flora, for in a fossilized state they are only found in the moet modern formations; in fact, the only fossilized Compositæ of which I know, were products of a river that fossilized everything thrown into it. Now it appeare that in the fight for existence the junior sons of creation have a decided advantage, and this accounts for the otherwise inexplicahle circumstance that the variety of organisms decreases so perceptibly when we enter the realms of *Gymnosperms*, vascular *Cryptogams* and all those forms of organic life that exieted already in the early periods of the earth.

Copper Mines of Winnemucca District, Nevada.—The price of copper has materially advanced in the past month or two, and copper mines are again heing sought for hy capitalists. This circumstance reminds ns of the fact that there are extensive copper-hearing leads in the Harmony range of mountains, within five miles of this town. One of these ledges crops out at intervals for a distance of half a mile, and specimens of the ore taken from the croppinge three feet ahove the surface of the ground carry 30% of metal. Numerous copper veins are known to exist in the range, only a few of which have been located, and all of which can he had at a trifling cost. Now that copper is going up, and is in demand, these minee ought to be developed. They are situated not more than five miles from the depot, and are easy of access at all seasons of the year. How permanent or valuahle they may he has to he determined, as none of them have been prospected to any extent, hut that the ledges crop out boldly and contain rich ores at the surface are indisputahle facts.—*Silver State.*

MECHANICAL PROGRESS.

Putting up Shafting.

The writer once had the putting up of considerable shafting, and following are some of the data respecting the same, the rules and formulas found in text-books being insufficient to form a correct opinion by. The writer found that 800 pounds, acting on the end of a 12-inch lever, would twist off a wrought-iron shaft one inch in diameter. The *length* of the shaft had no influence on the breaking or twisting-off force, or torsional strength of the shaft, though on the length depended the torsional elasticity. The speed of a shaft controls its size, that is, if a one-inch shaft is large enough to transmit a given force at 50 revolutions per minute, a shaft running at 100 revolutions per minute will transmit the same force, its *area* being one-half of the one-inch shaft. This is plain enough when one remembers that the surface of a pulley on the smaller shaft travels *twice* as far in the same time that a similar surface on a similar pulley on the slower shaft travels, and hence needs transmit but half the force, to equal the force through half the distance.

Suppose we have a factor of safety of 4, this will allow of our continuing a force of 200 lbs. (800 ÷ 4 = 200) on the end of our 12-inch lever. That is, 200 will be a safe load. Now, if we wish to find the *area* of a shaft, to transmit 10 H. P. at a speed of 300 revolutions per minute, over a 24-inch pulley, we multiply 33,000 feet (one H. P.) by 10 H. P., obtaining 330,000, which, divided by the number of feet the run of the pulley passes through per minute (6.28 ft. + 300 revolutions), will equal the strain on the end of a lever equal to the radius of the pulley. In this case supposed, the radius of the pulley equals 12 inches, the size of the one for comparison. If it had not it would have been necessary to reduce it to 12 inches, that is, the effect the force would have at 12 inches. This force, whatever it may be, then being divided by 200 (the safe load on a one-inch shaft) will equal the area of the needed shaft, that is, it will equal the area in units of the area of a round shaft one inch in diameter—7,854-10,000ths of a square inch.

To reduce the radius of the pulley, whatever it may be, to the standard of the unit of comparison—12 inches—suppose the pulley was 40 inches in diameter, the radius is 20 inches. If the force as found were 50 lbs., we would multiply the 20 inches by 50, and divide the product by the length of our standard lever, 12 inches. The result being the weight necessary at the end of a 12-inch lever that would be equal to the force or strain on the belt over the pulley. For instance, let us take the conditions of the case given: Number of feet raised one foot high in *one* H. P. × 10 = 330,000. Circumference of pulley = 6.28 feet, which multiplied by 300 = 1,884 feet per minute, that the rim of the pulley moves through; 330,000 ÷ 1,884 = 175.15, that is 175.15 lbs. is the constant strain on the belt, because 175.15 lbs. through 1,884 feet = 10 H. P. = 330,000.

This steam is transmitted to the pulley which acts as a lever, equal to the radius of the pulley, tending to twist off the shaft. The radius of the lever in this case is 12 inches, which happens to be the same as our lever of comparison.

Thus we have a force of 175.15 lbs. acting on the end of a 12-inch lever; 200 lbs. on the end of a 12-inch lever was, as previously stated, a safe load for a one-inch round shaft; 175.15 ÷ 200 = .875 = ⅞ of the area of a shaft one inch in diameter = .6872 of a square inch, and would be a trifle over nine-tenths of an inch in diameter.

Thus, so far as torsional strength is concerned, a one-inch round iron shaft will transmit with safety 10 H. P.; but there is another feature of the question to be looked after, and that is the lateral stiffness of the shaft.
